## PREFACE TO THE THIRD EDITION.

---

ON account of the revision of the Pharmacopœia and the introduction of many new compounds into medicine, a revised edition of this work seems desirable. The general arrangement remains unchanged. About fifty new prescriptions are introduced, replacing some that are less important or are duplicated to some extent.

Acknowledgment is made of the assistance of Dr. R. H. Smith in getting up the table of solubilities. Thanks are returned to the many friends who have sent in prescriptions for comment.

VANDERBILT UNIVERSITY, 1908.

iii

## PREFACE TO THE SECOND EDITION.

---

IN this edition Part I has been entirely rewritten. Many of the statements made in the first edition have been gone over in the Author's laboratory; a few were found to be incorrect, while a modification of others was necessary. In performing the laboratory work the fact was again emphasized that many conditions, such as temperature, dilution, order of mixing, impurities in commercial drugs, etc., materially affect the results obtained. The text of this part of the book has been made rather full so that as a reference book it may have some value. At the same time the insertion of numbers at the beginning of the statements makes it easy for the teacher using the book to designate what incompatibilities he wishes the student to learn.

Some changes and additional statements have been made in Part II. Twenty-five prescriptions with comments have also been added as well as fifty prescriptions without comments. The comments on the last were omitted so that the student can the better test his knowledge.

Since so many incompatibilities are the result of the formation of insoluble compounds it was deemed advisable to introduce a table of solubilities for reference. A table of average prices charged for prescriptions not requiring particular skill or calling for expensive ingredients is also appended, so that those who have not had the drug-store experience may have some idea as to the general prices charged. Attention is called to the complete index of prescriptions

which enables one to find at a glance any prescription containing a certain ingredient or combination of ingredients that is given in the book.

The Author has found this book to be of as much value to medical students as to those in Pharmacy. Since the incompatibility in a prescription originates with the physician, if the subject were better understood by the writer of the prescription there would be less trouble both for physicians and pharmacists.

The Author wishes to thank his many friends for the generous words of encouragement that they have given him.

VANDERBILT UNIVERSITY, June, 1900.

## PREFACE TO THE FIRST EDITION.

---

THE busy prescriptionist is frequently at a loss to know what takes place in the prescription he is filling, and does not have the time nor books necessary to look up the change which he has noticed. The object of the first part of this book is to present to him in a convenient and condensed form the more common incompatibilities. The substances treated of are arranged in alphabetical order of their Latin names, except in case of some of the newer remedies. In order to avoid repetition all the incompatibilities of each substance are not always given under that heading. For instance, the reaction between two substances may be found under the heading of one of the substances and not under the other.

The second object of the writer is to furnish the student of pharmacy with a list of incompatible prescriptions in such form that he may find out for himself what the trouble is, and the best means of avoiding or overcoming it. It is suggested that he study the prescription thoroughly before referring to the notes.

Acknowledgment is hereby made of assistance received from all of the books and journals mentioned in the list of abbreviations of references.

EDSEL A. RUDDIMAN.

## PART I.

### INCOMPATIBILITIES.

**Acacia.**—1. Mucilage of acacia is about neutral to litmus on account of the lime water in it. An aqueous solution of acacia is acid to litmus, but is not sufficiently acid to cause trouble unless decomposition has commenced. 2. The official mucilage of acacia is gelatinized by a **solution of ferric chloride, tincture of ferric chloride, solution of ferric sulphate, or solution of ferric subsulphate.** Alkali citrates in small proportions, alkali acetates in larger proportions, excess of hydrochloric or other acids, or dilution with water, will tend to prevent coagulation. One volume of tincture of iron with an equal volume of water will give a solution with one volume of mucilage diluted with an equal volume of water. Different samples of tincture chloride of iron vary in the amount of free acid and this causes a variation in the amount of citrate, acetate, acid, or dilution necessary to prevent gelatinization. Glycerin or syrup seems to have but little more effect in preventing coagulation than so much water. The color of the mixture of the iron salt and the mucilage is deeper red than that of the tincture alone. Gelatinized acacia will afterwards slowly dissolve if an excess of water is added. 3. **Solution of dialyzed iron** when mixed with mucilage of acacia forms gelatinous masses, having the color of ferric hydroxide, but does not give a translucent mass as does the tincture of iron; dilution with water or the addition of a citrate has but little effect in preventing precipitation. 4. The **solution of ferrous chloride (N. F.), iron citrate, iron and ammonium citrate, or a saturated solution of ferrous sulphate** does not gelatinize mucilage of acacia. 5. A saturated solution of **borax** forms a more or less translucent mass with mucilage of acacia. By diluting the borax solution with an equal volume of water,

and the mucilage with an equal volume of water, no coagulation takes place. The coagulation may also be prevented by adding three or four drops of glycerin or honey to one dram of the borax solution, or by acidifying the borax solution. Either glycerin or honey decomposes borax to some extent, liberating boric acid, but not enough need be added to make the solution acid. The official syrup or a solution of glucose tends to prevent the coagulation, but is not as effective as glycerin. 6. A solution of **lead subacetate** (not the neutral lead acetate), even if quite highly diluted, will give white, opaque, gelatinous masses when mixed with mucilage of acacia. Diluting the mucilage with several volumes of water does not prevent coagulation although glycerin and syrup do to some extent. 7. Mucilage containing lime water will have many of the incompatibilities of lime water. 8. Acacia is nearly insoluble in **alcohol**. The mucilage can be mixed with a little over one half its volume of alcohol without permanent precipitation. If the mucilage is first diluted with water a stronger alcoholic mixture can be obtained before precipitation is permanent. The precipitate redissolves on subsequent dilution with water. 9. **Sulphuric acid** converts acacia into arabic and then metarabic acid and precipitates calcium sulphate (U. S. D., 5). Dilute sulphuric acid converts it into a sugar on prolonged boiling (M. & M., I. 296). A strong solution of a sulphate gives a precipitate of calcium sulphate. 10. Dilute **nitric acid** converts acacia into mucic, saccharic, oxalic, and tartaric acids (U. S. D., 5). 11. In the presence of acacia, dilute solution of salts of **mercury, lead, copper, antimony, silver, iron, or arsenic** do not give precipitates with **hydrogen sulphide** or **alkaline sulphides**, although a coloration may be produced. 12. Acacia prevents the precipitation of dilute solutions of salts of **mercury, antimony, aluminum, iron, calcium**, and some other metals by **alkali hydroxides** or **borax** and in some cases by **carbonates**. 13. Dilute solutions of **alkaloidal salts** in the presence of acacia are not precipitated by **potassium mercuric iodide, sodium phosphomolybdate, or tannic acid** (Allen, I. 426). These properties are common to many gums (M. & M., I. 296). The solution of the alkaloid must be very

dilute or some precipitation will occur. 14. Mucilage of acacia is colored blue, either at once or after standing a short time, by a tincture of **guaiaac** if the guaiac is fresh, but not with a guaiac that has been exposed to air and light for some time. A mucilage made from acacia tears may give the blue when one made from powdered acacia will not. This is probably due to a ferment in the tears which is destroyed by the heat necessary before powdering. Heating a mucilage of acacia to 100° C. for one hour destroys the ferment, without impairing the emulsifying powers (Ph. J., 1905, 620). 15. Bourquelot (Pharm. Zeitrh., Aug. 10, 1905, Am. D., XLVII, 239) states that acacia contains an oxydase which gives colors when a ten per cent. solution of acacia is mixed with a one per cent. solution of carbolic acid, naphthol, pyrogallol, cresol, thymol, guaiacol, vanillin, pyramidon, morphine, apomorphine, physostigmine, adrenalin, barbaloin, tannin, preparations of tar, and other compounds.

**Acetanilidum.**—1. With **spirit of nitrous ether**, **amyl nitrite**, or a solution containing **nitrous acid**, acetanilide gives a yellow solution, becoming red on standing for some time. With a fresh or nearly neutral spirit of nitrous ether the yellow coloration may not be noticed for several days and the red for two weeks or more. The presence of an alkali or a little sodium bicarbonate will prevent the appearance of more than a pale yellow within a month. Probably diazo-compounds are formed. 2. A cold **solution of ferric chloride** with acetanilide gives no increase of color, but, if heated, it assumes a deep red color which fades as the solution cools. If heat is applied to a concentrated solution for several minutes a dark green color is produced. With the **tincture of iron** acetanilide gives a red color without heating, because acetanilide is soluble in alcohol. Excess of acid lessens the color. 3. **Bromine, iodine, bromides, or iodides** do not precipitate aqueous solutions of acetanilide unless they are added in very large excess. 4. **Acids** generally hydrolyze it (Ph. R., XXI., 73). 5. Acetanilide is slowly decomposed by a strong solution of **potassium** or **sodium hydroxide**, forming anilin (N. S. D., 8). 6. A mixture of acetanilide and **calomel**, either dry or with water,

shows no perceptible change within a month and gives no test for a mercuric salt. 7. Rubbing acetanilide with **chloral alcoholate**, **piperazine**, **phenol**, **pyrocatechin**, **resorcin**, or **thymol** produces a soft mass or liquid which is soluble in alcohol and insoluble or only partly soluble in water. 8. Heavy trituration of acetanilide with **antipyrine** or **chloral hydrate** gives a damp powder. 9. **Chloral hydrate** increases the solubility of acetanilide in water; a mixture of ten grains of chloral hydrate with one grain of acetanilide will dissolve in about five minims of water and further addition of water does not cause precipitation. 10. When **sodium salicylate** is mixed with acetanilide a pink powder is said to be produced, but the writer did not get much increase of color, although the paper containing the mixture became colored after a time. 11. Acetanilide is said to be readily soluble in a hot solution of **tartaric acid** from which it does not crystallize. However, the writer did not find this to be the case.

**Acetozone**, *Benzoyl-acetyl Peroxide*.—1. Acetozone is hydrolyzed by **water** and decomposed in contact with solutions of **alkalies** or heated with **water** (N. S. D., 222). 2. Heating, grinding, compressing or pounding will often bring about a decomposition (U. S. D., 1411). 3. Gradually decomposed by all solvents except neutral petroleum oils (U. S. D., 1411).

**Acetphenetidinum**. [See PHENACETINUM.]

**Acida**.—1. Acids combine with **metallic oxides** and **hydroxides**, with some **metals**, and with some **alkaloids** to form salts. 2. Mineral acids and some organic acids, such as tartaric or acetic, precipitate bismuth citrate from solutions of **bismuth and ammonium citrate** by combining with the ammonium. 3. Mineral and common organic acids precipitate potassium bitartrate from concentrated solutions of **Rochelle salt**, normal **potassium tartrate**, or double tartrates containing potassium. 4. Nitric, hydrochloric, or sulphuric acid with an aqueous solution of **tartar emetic** gives a precipitate consisting of a basic nitrate, chloride, or sulphate of antimony. The presence of tartaric acid prevents precipitation, the amount of acid necessary seeming to depend upon the amount of mineral acid used. 5. Mineral acids give a precipitate of

the phosphate or the pyrophosphate of iron when added to a solution of the official **soluble phosphate** or **pyrophosphate of iron**. 6. Strong mineral acids precipitate, from concentrated solutions of **borates**, **salicylates**, or **benzoates**, the boric, salicylic, or benzoic acid. 7. Strong mineral acids form esters and ethers with **alcohol**. Many organic acids in the presence of mineral acids, as sulphuric or hydrochloric, form esters with alcohol. 8. Nearly all acids, except hydrocyanic and hydrosulphuric, decompose **carbonates**, liberating carbon dioxide. 9. Acids diminish or prevent the action of **pancreatin**. 10. Many acids precipitate **albuminous substances** from aqueous solution. 11. Organic acids, except acetic, combined with an alkali, generally form compounds with the **heavy metals**, that are insoluble in water. 12. Frequently mineral acids displace organic acids and the stronger mineral acids the weaker ones.

The following official preparations contain a free acid: 13. the vinegars of opium and squills; 14. hydrogen dioxide water; 15. citrated caffeine; 16. fluidextracts of conium, ergot, lobelia, nux vomica, and sanguinaria, squills; 17. fluidextracts in general are acid to litmus, some sufficiently acid to liberate carbon dioxide from carbonates; 18. glycerites of tannic acid, boro-glycerin, and iron quinine and strychnine phosphates; 19. solutions of arsenous acid, ammonium acetate, chlorine compound, chloride of iron, iron and ammonium acetate, subsulphate of iron, tersulphate of iron, nitrate of mercury, sodium phosphate compound, and zinc chloride; 20. all of the oleates; 21. spirit of nitrous ether, usually; 22. syrups of citric acid, hydriodic acid, calcium lactophosphate, hypophosphites, hypophosphites compound, ipecac, iron quinine and strychnine phosphates, and squills; 23. tinctures of chloride of iron and sanguinaria; 24. ointments of boric acid, tannic acid, and usually mercuric nitrate. 25. Besides these there are some substances which become acid on exposure, as acetic ether, spirit of nitrous ether, amyl nitrite, and oil of bitter almonds.

26. There are quite a number of salts that are acid in re-

action and sufficiently so to give an effervescence with a carbonate. Some of the more common are: alum, aluminum sulphate, bismuth subnitrate, ferric chloride, ferric citrate, iron and quinine citrate, iron and strychnine citrate, ferrous sulphate, lead nitrate, quinine bisulphate, zinc acetate, zinc chloride, and zinc sulphate.

**Acidum Aceticum.**—1. Acetic acid decomposes nearly all **carbonates**, liberating carbon dioxide and forming acetates. 2. It forms chloracetic acid with **chlorine**, slowly in diffused light, more quickly in sunlight. 3. Soluble neutral acetates, or the free acid if it is concentrated and the solution of iron salt is weak, with solutions of **ferric salts**, give a deep red coloration. The color varies from a yellow red to a dark red, according to the dilution, due to the formation of ferric acetate, which on heating precipitates as the basic ferric acetate. The strong mineral acids in excess prevent the formation of the color. 4. Acetic acid aids the solution of **quinine sulphate** in water, increasing the fluorescence. This solution does not precipitate on standing, but on adding potassium acetate the fluorescence is destroyed and, if it is a fairly strong solution of quinine, needle-shaped crystals will be formed in a few minutes. Experiments made indicate that double decomposition takes place, forming quinine acetate and potassium sulphate. The precipitation may be due partly to the quinine acetate being only sparingly soluble and partly to the quinine salt being less soluble in a solution of potassium acetate. The precipitate formed may be dissolved by the further addition of acetic acid and again thrown down by adding potassium acetate, the amount of potassium acetate necessary seeming to depend on the excess of acetic acid used. It may be that the potassium acetate combines with the acetic acid (as explained in R. & S., III. part I. 497), forming potassium diacetate, thus taking up the free acid. Potassium acetate in sufficient amount will destroy the fluorescence and give a precipitate with a solution of quinine bisulphate or quinine sulphate dissolved in water by the aid of sulphuric acid. It has been suggested that

quinine hydrate is formed, the acetic acid being too weak to hold the hydrate in solution (M. R., ix. 158). 5. A mixture of **alcohol**, **sulphuric acid** and acetic acid or an acetate gives ethyl acetate, which has a fruity odor. 6. An aqueous solution of potassium acetate with **spirit of nitrous ether** produces an effervescence. Nitrous acid in strong solution converts acetates into carbon monoxide and other gases (Scoville, 301). The effervescence may be due to the potassium acetate throwing the volatile ethyl nitrite out of solution; salts upon which ethyl nitrite has no action cause a similar effervescence. 7. The stronger **mineral acids** transpose acetates, liberating acetic acid. 8. Acetic acid is not sensibly affected by **nitric acid** or readily changed by **oxidizing agents**. 9. Strong acetic acid is a good solvent for **resins**, **gum-resins**, **camphor**, and **volatile oils**. 10. Some acetates, as lead, on being exposed to the **air** lose acetic acid and absorb carbon dioxide, becoming partly insoluble. 11. Nearly all normal acetates are readily soluble in water, except quinine, silver, and mercurous. The acetates, except silver and mercurous, are generally soluble in alcohol. [See ACIDA.]

**Acidum Benzoicum.**—1. Benzoic acid combines with the **hydroxides** of the **alkalies** and **calcium** to form benzoates. 2. It liberates carbon dioxide from **carbonates**. 3. Soluble benzoates precipitate nearly neutral solutions of **ferric salts** as ferric benzoate, which is flesh colored. The presence of an excess of free acid or of alkali tartrates or citrates interferes with or prevents the precipitation. 4. Sodium benzoate gives precipitates with solutions of salts of **silver**, **mercury**, and **lead**, the latter being somewhat soluble in excess of lead acetate. 5. Sodium benzoate gives a white, sticky precipitate when it is added to a solution of **quinine bisulphate** or to a slightly acidulated solution of **quinine sulphate** if the quinine solution is not too dilute. Quinine benzoate is soluble is about 370 parts of water and more soluble in alcohol. 6. **Hydrogen dioxide** with a little sulphuric acid converts benzoic acid into salicylic acid (M. & M., i. 470). 7. Benzoic acid is not readily attacked

by **nitric** or **chromic acid**. 8. Concentrated aqueous solutions of benzoates give a crystalline precipitate of benzoic acid when dilute solutions of strong **acids** are added. Some acids in fruit syrups precipitate benzoic acid when sodium benzoate is used as a preservative. 9. The solubility of the free acid in water is increased by the presence of borax, alkali citrates, sodium phosphate, or sodium sulphite. 10. Most benzoates are soluble in water and many are soluble in alcohol. The more sparingly soluble benzoates dissolve readily in aqueous solutions of sodium acetate, lead acetate, or sodium nitrate (Storer, 61). [See ACIDA.]

**Acidum Boricum.**—1. Boric acid combines with the **hydroxides** of the **alkalies** and the **alkaline earths** to form borates. 2. It decomposes **carbonates** of the **alkalies** and of the **alkaline earths**, liberating carbon dioxide, but under certain conditions carbon dioxide may decompose borates. 3. The alkali borates, as borax, give precipitates with nearly neutral solutions of salts of several **metals**, the precipitate being more or less soluble in excess of the metallic salt or in the presence of ammonium chloride (Watts, 1. 641); 4. with **mercuric chloride** the precipitate is red-brown basic mercuric chloride (Watts, 1. 641); 5. with **silver nitrate** the precipitate is silver borate (sometimes mixed with a little oxide); 6. with **lead acetate**, **barium chloride**, or **calcium chloride** the precipitate is a borate of the metal (P. & J., 246); 7. with **alum** the precipitate is aluminum hydroxide; 8. with **zinc sulphate** the precipitate may be chiefly a borate or a mixture of the borate with a basic compound (Watts, 1. 649); 9. with **ferric salts** a basic borate is formed (Watts, 1. 530). 10. Concentrated solutions of borates give a precipitate of boric acid with nearly all **mineral acids**. 11. Borax with many of the weaker **acids** forms double salts in which boric acid seems to act the part of a base. When borax and **tartaric acid** are mixed in solution in proper proportions boric acid separates; if the quantity of tartaric acid is gradually increased, the quantity of boric acid also increases up to a certain point, beyond which it decreases, acting the part of a base (Watts,

1. 648). 12. Borax is alkaline in reaction and precipitates the **free alkaloids** from aqueous solutions of their salts. This can be prevented by first mixing a little glycerin with the borax. 13. **Glycerin** and borax react in the presence of water, liberating boric acid. [See GLYCERIN, No. 1.] Glucose, some other forms of sugar, and honey cause a similar reaction. 14. In solution borax decomposes **chloral hydrate**, liberating chloroform. 15. When triturated with alum, benzoic, gallic, salicylic, or tartaric acid, borax gives a damp powder or sticky mass. Chemical reaction takes place and water of crystallization is liberated. 16. Borax coagulates mucilage of **acacia**. [See ACACIA, No. 5.] 17. Borax increases the solubility in water, of **boric, benzoic, salicylic** and **stearic acids, potassium bitartrate, oils** and **resins**. It aids the suspension in water of oils and resins. 18. The solubility of the free acid in water is increased by the presence of **tartaric acid, potassium tartrate, Rochelle salt, potassium citrate** and **borax**, the salts being partially decomposed (Watts, 1. 648). 19. An aqueous solution of a mixture of boric and salicylic acids gives a precipitate with solutions of **alkaloidal salts** under certain conditions. One grain of an alkaloidal salt added to an ounce of water containing one grain of salicylic acid and ten grains of boric acid generally gives a precipitate. If the ounce of water contains one half the amount of acids given above no precipitate is formed by cocaine hydrochloride, morphine sulphate, codeine sulphate or atropine sulphate. Quinine bisulphate and strychnine give precipitates when one ounce of water contains one fourth of a grain of salicylic and two and one half grains of boric acid, but not when one half this proportion of acids is used. 20. The solubility of borax in water is increased by **sugar**. 21. The borates, excepting those of the alkalies, are nearly insoluble in water, but are generally soluble in the presence of free boric, tartaric, or mineral acid. They are insoluble in alcohol.

**Acidum Camphoricum.**—1. Camphoric acid combines with **alkalies, calcium, barium, and magnesium**, to form soluble salts (N. S. D., 38).

**Acidum Chrysophanicum.**—1. Chrysophanic acid is dissolved by aqueous solutions of **alkalies**, forming a liquid which is pink when dilute and dark purplish-red when concentrated. This solution, when neutralized with acids, precipitates the yellow chrysophanic acid (Allen, III. part I. 262). 2. An ammoniacal solution of chrysophanic acid gives a lilac-colored precipitate with **acetate of lead** and rose-colored with **alum** (Allen, III. part I. 262).

**Acidum Citricum.**—1. Citric acid forms citrates with most metallic **hydroxides** or **carbonates**, with most **acetates**, with **alkaline sulphides**, and with **soap**. 2. With a strong solution of **potassium tartrate** or **Rochelle salt** citric acid forms sodium citrate and potassium bitartrate which is precipitated. 3. A strong solution of citric acid gives a precipitate with a solution of **bismuth** and **ammonium citrate**, but it may take several hours. 4. Soluble citrates and citric acid when heated with **lime water** give a precipitate of calcium citrate. 5. Neutral soluble citrates precipitate solutions of **lead acetate** and **silver nitrate** as citrates, both being soluble in excess of the precipitant. 6. The normal magnesium citrate is sometimes precipitated in the official **solution of magnesium citrate** when the citric acid is not present in considerable excess. 7. An alkaline solution of a citrate with **chlorine** gives some chloroform (M. & M., II. 194). 8. Citric acid is oxidized to acetic and oxalic acids by concentrated **nitric acid** (P. & J., 252); it is scarcely attacked by dilute nitric acid (Watts, I. 996). 9. An acidulated solution of **potassium permanganate** oxidizes it to carbon dioxide and acetone (Allen, I. 531), and is slowly decomposed. 10. **Heating** citric acid until all its water of crystallization is driven off, aconitic acid will be produced (U. S. D., 28). 11. Neutral or nearly neutral solutions of salts of **aluminum**, **iron**, **nickel**, **manganese**, **antimony**, **mercuric mercury**, **copper**, **zinc**, **chromium**, **calcium**, or **magnesium**, in the presence of the alkali citrates, are not generally precipitated by the alkali **hydroxides**, **carbonates**, **phosphates**, or by **borax**. The citrates also sometimes prevent precipitation of the metals by **oxalates**

and **sulphates**. In many instances there are double compounds formed. If heat be applied precipitation may take place. 12. The insoluble citrates are transposed by the dilute **mineral acids**. 13. When a drug containing **tannin** is added to a mixture of a **ferric salt** and an alkali citrate there is a darkening, but the citrate to a slight extent prevents the formation of the black tannate of iron. 14. Citric acid aids the solution of **quinine sulphate** in water and the solution is fluorescent. If an alkali citrate is now added to this the fluorescence is destroyed and in a few minutes a crystalline precipitate forms. This may be dissolved by the further addition of citric acid or a mineral acid. Quinine citrate is soluble in 900 parts of water (N. S. D., 1289). 15. The presence of an alkali citrate increases the solubility in water of some acids as **gallic**, **salicylic**, and **benzoic**. 16. Potassium citrate dissolved in dilute **alcohol** (one part of the salt to six of the solvent) causes the liquid to separate into two layers, the upper being nearly twice the volume of the lower. Potassium citrate is insoluble in alcohol and in separating takes some water with it. 17. The citrates of the alkalies are soluble in water; those of iron, zinc, and copper are moderately soluble; the other single citrates are nearly insoluble. Citric acid in excess converts the insoluble citrates into the more soluble acid citrates, and the alkali citrates convert them into the more soluble double citrates. [See ACIDA.]

**Acidum Gallicum.**—1. An aqueous solution of gallic acid soon decomposes when exposed to air, giving off carbon dioxide, turning yellow, brown, and black, and depositing a black substance; this coloration is hastened by alkali hydroxides and in alkaline solution the gallic acid is converted into galloflavin (Richter, II. 230). 2. Gallic acid combines with **alkali hydroxides**. In mixtures of the acid and a solution of potassium or sodium hydroxide, when the acid is in excess, the color becomes green; when the alkali is in excess, the color is yellow, changing to red and brown. 3. Gallic acid in excess with **ammonia water** gives a yellow color, but when the ammonia is in excess the color is red brown. 4. It decomposes alkali

**carbonates** liberating carbon dioxide and producing colorations similar to those given when added to fixed alkali hydrates. 5. With an excess of **sodium bicarbonate** a solution of gallic acid turns brown, then green and ultimately blue, and gives a precipitate of a deep blue-green solid. 6. Gallic acid with **lime water** in excess gives a blue-white precipitate, and the liquid acquires a tint which is blue by reflected and green by transmitted light, and becomes pink with a large excess of lime water. If the acid is in excess the color is brown. 7. Gallic acid gives a blue-black solution or precipitate with a solution of **ferric chloride**. With an excess of the iron the color is green blue to a green brown. Heat changes the blue-black color to brown, probably due to the reduction of the ferric iron to the ferrous condition, and to the conversion of gallic acid into pyrogallic or metagallic acid. 8. Gallic acid with a strong solution of a pure **ferrous salt** gives a white precipitate. On exposure to air the mixture soon becomes colored, due to the oxidation of the iron. 9. With a solution of **potassium cyanide** gallic acid gives a transient red color. 10. With a solution of **tartar emetic** it gives a precipitate of gallate of antimony; in dilute solution the precipitation is prevented by ammonium chloride. 11. Gallic acid produces a precipitate when added to a solution of **lead acetate**. 12. It reduces salts of **silver** and **gold** to the metals. 13. Oxidizing agents, such as **arsenic acid** and **iodine**, with water, convert gallic acid into elagic acid (Richter, II. 230). Iodine with gallic acid gives hydriodic acid and oxidation products of gallic acid (N. S. D., 826). Arsenic converts it into tannic acid without the production of arsenous acid (Chem. News, xxix. 73). 14. Triturating gallic acid with **potassium permanganate** may cause the acid to take fire. 15. With **spirit of nitrous ether** gallic acid or a solution of gallic acid produces an effervescence and gives a red color. 16. Gallic acid does not precipitate solutions of alkaloids, gelatin, albumin, or starch, but a mixture of **gum acacia** and **gelatin** is said to be precipitated. 17. The solubility in water of the free acid is increased by borax or alkali citrates. 18. The gallates of the alkalies are soluble,

but the others are nearly insoluble in water and generally insoluble in alcohol.

**Acidum Hydriodicum.**—1. Hydriodic acid or syrup of ferrous iodide on being exposed to **air** and **light** liberates iodine; the hypophosphorous acid in them prevents the change for a time. Exposed to sunlight for a month eighty per cent. of the hydriodic acid is decomposed (M. R., XII. 228). Ammonium iodide is soon decomposed by air and light, potassium iodide much less quickly, particularly if it contains a little potassium carbonate. 2. Solutions of iodides with dilute mineral **acids** or some organic acids liberate hydriodic acid, which is more or less quickly oxidized to iodine by the oxygen of the air. Some neutral salts, as ammonium nitrate, tend to decompose iodides. 3. Hydriodic acid and soluble iodides precipitate solutions of salts of **lead**, as the bright yellow lead iodide. This is prevented to some extent by alkali acetates. 4. They precipitate salts of **silver**, as the yellow-white silver iodide; of **mercurous mercury**, as the yellow mercurous iodide; of **mercuric mercury**, as the red mercuric iodide. 5. The alkali iodides in excess form double compounds with **lead**, **silver**, and **mercuric iodides**, which compounds are soluble. The solution of the double salt of mercuric and potassium iodide  $(KI)_2HgI_2$  is known as "Mayer's reagent," and precipitates nearly all alkaloids from their aqueous solutions. Potassium iodide given with insoluble mercury preparations makes them more soluble and active. (A. J. P., XXVI. 222). 6. **Mercurous iodide** with an excess of potassium iodide in the presence of water is decomposed, forming metallic mercury and mercuric iodide, the latter combining with potassium iodide to form the potassium mercuric iodide. 7. **Calomel** with water and an excess of potassium iodide forms mercurous iodide and potassium chloride; the mercurous iodide is decomposed as given under No. 6. 8. Soluble iodides reduce **cupric salts** in solution and give a white precipitate of cuprous iodide; at the same time the solution turns red, due to the liberation of iodine. 9. Soluble iodides with **ferric salts** in acid solutions reduce the ferric to ferrous

iron, but give no precipitate of iron; iodine is liberated and, if all of the iodide is decomposed, may be precipitated. 10. When **bismuth subnitrate** is added to syrup of hydriodic acid it is changed to a yellow substance at once which further changes to orange red and then to dark gray. Sometimes the ultimate precipitate seems to consist of two different substances, one yellow and the other gray. When bismuth subnitrate is added to a solution of potassium iodide it assumes a yellow color in a few hours and within a day it has changed to a deep red. The color varies with the iodide formed;  $\text{BiOI}$  is red;  $3\text{BiOI}, 4\text{Bi}_2\text{O}_3$  is yellow;  $\text{BiI}_3$  is dark gray (M. & M., I. 513). Sodium bicarbonate in an amount equal to that of bismuth prevents the change. Diluted hydrochloric acid causes the coloration to take place at once. Syrup of ferrous iodide gives a yellow color at once, turning red brown in a short time. 11. **Spirit of nitrous ether**, and **nitrites** in acid solution, liberate iodine from iodides and give off oxides of nitrogen. 12. **Nitric** or **nitrohydrochloric acid** liberates iodine from iodides and, if sufficiently concentrated, oxidizes it to iodic acid. 13. **Chlorine** oxidizes iodides, forming iodine then iodic acid and in an alkaline mixture a periodate. The chlorine is changed to a chloride. 14. **Chlorates** in an acid solution of an iodide liberate iodine and then change it to iodic acid which is more toxic. Probably a similar reaction takes place in the stomach when a chlorate and an iodide are taken together. 15. **Iodates** in acid solution with iodides liberate iodine from both. Iodides sometimes contain iodates as impurities, hence the liberation on adding an acid. 16. **Arsenic compounds** in acid solution with iodides liberate iodine and become arsenous. 17. A solution of potassium iodide with **arsenous acid** or **potassium arsenite** yields a precipitate of  $2\text{KI}, 3\text{As}_2\text{O}_3$ , which is sparingly soluble in cold water (Watts, I. 377). When one dram of potassium iodide is added to one fluid dram of the U. S. P. solution of potassium arsenite, a white precipitate forms in a few hours; if half that amount of iodide is added the precipitation may not take place for several days.

18. **Chromates** in acid solution liberate iodine and form chromic salts. 19. **Permanganates** in acid solutions liberate iodine and, if in great excess, oxidize it to iodic acid. 20. **Hydrogen dioxide** in acid solution liberates iodine from iodides, slowly in neutral mixtures. 21. The iodides sometimes contain carbonates and would then have the incompatibilities of the carbonates. 22. The alkali iodides precipitate aqueous solutions of many **alkaloidal salts**. In some cases this is due to the formation of compounds that are less soluble in water than the original salt. When a large excess of the alkali iodide is used it may render the alkaloidal salt less soluble in the solution than it is in water. The precipitation in other cases is due to the carbonate occurring as an impurity in the iodide. The presence of alcohol prevents the precipitation to a considerable extent. The prescribing of strychnine sulphate with potassium iodide is particularly dangerous because the precipitation may not take place for some time. A solution of one twelfth of a grain of strychnine sulphate with five grains of potassium iodide and two drams of water does not usually precipitate at once, but may do so within a few hours. 23. The lead, silver, mercurous, mercuric, cuprous, bismuth, and stannous iodides are nearly insoluble in water; all others are soluble. Nearly all iodides, except lead, silver, and mercurous, are soluble in alcohol. [See ACIDA.]

**Acidum Hydrobromicum.**—1. The soluble bromides and hydrobromic acid precipitate solutions of salts of **lead, silver, and mercurous mercury** as bromides. 2. In concentrated aqueous mixtures alkali bromides form double soluble compounds with lead or silver bromide, which double compounds are broken up by a large amount of water. 3. An aqueous solution of an alkali bromide or of hydrobromic acid causes **calomel** to turn black and the filtrate gives a test for a mercuric salt. Probably a reaction takes place similar to the one explained under **ACIDUM HYDRIODICUM**, Nos. 6 and 7. 4. Dilute hydrobromic acid with **bismuth subnitrate** gives a mixture in which the liquid has a pale yellow color. With

potassium bromide there is no apparent change. 5. Bromides with **nitric acid** give bromine. 6. **Chlorine** forms bromine and hydrochloric acid. In alkaline mixtures a bromate is formed. 7. **Chlorates** in acid solution give bromine and hydrochloric acid. 8. Bromides in acid solutions reduce **permanganates** to manganous salts and liberate bromine. 9. **Chromates** in acid solution with bromides form chromic salts and bromine. 10. The alkali bromides precipitate some of the **alkaloids** from the solutions of their salts similar to the alkali iodides [see **ACIDUM HYDRIODICUM**, No. 22] but are not as apt to do so. The presence of alcohol generally prevents this precipitation. 11. The alkali bromides sometimes contain carbonates as impurities and would then have the incompatibilities of carbonates and the solution would be alkaline. 12. The metallic bromides are soluble in water, except lead, mercury, silver, copper, and bismuth. They are generally somewhat soluble in alcohol. [See **ACIDA**.]

**Acidum Hydrochloricum.**—1. Hydrochloric acid and the soluble chlorides precipitate as chlorides solutions of salts of **lead**, **silver**, and **mercurous mercury**. 2. With a solution of **tartar emetic** hydrochloric acid gives a precipitate of basic chloride of antimony. 3. Hydrochloric acid with **chlorates** gives chlorine and various chlorides of oxygen. 4. Concentrated hydrochloric acid with concentrated **nitric acid** gives chlorine and oxychlorides of nitrogen. 5. **Permanganates** liberate chlorine from hydrochloric acid and are reduced to manganous chloride. 6. **Chromates** form chromic chloride and free chlorine. 7. Bismuth citrate is precipitated from a solution of **bismuth and ammonium citrate** when hydrochloric acid is added to it. 8. Some writers say that chlorides aid the conversion of **calomel** to mercuric chloride. [See **HYDRARGYRUM**, No. 7.] 9. The soluble chlorides give hydrochloric acid when treated with **sulphuric acid**. 10. Hydrochloric acid, being stronger than most other acids, except sulphuric and nitric, very frequently displaces other acids when they are combined with bases. 11. The soluble chlorides when added so as to make a con-

centrated solution with a solution of an **alkaloidal salt** may precipitate the alkaloid. 12. Hydrochloric acid added to an alcoholic solution of **myrrh** slowly gives a red to a violet color; added to an alcoholic solution of **balsam of Tolu** it gives a yellow color, changing through brown to cherry red; with many **resins** a brown color is produced. 13. The normal chlorides, except lead, mercurous, and silver, are soluble in water. Many of the chlorides are soluble in alcohol. [See ACIDA.]

**Acidum Hydrocyanicum Dilutum.**—1. The aqueous solution of hydrocyanic acid decomposes into the formate of ammonium, cyanic acid, and other compounds, depositing paracyanogen. 2. Potassium cyanide in aqueous solution is decomposed on standing, giving potassium formate and ammonia (Watts II. 218). 3. An aqueous solution of potassium cyanide is quite strongly alkaline, and this alkalinity increases with exposure, due to the absorption of carbon dioxide and the volatilization of the hydrocyanic acid. 4. Concentrated **mineral acids** produce formic acid and a salt of ammonium (Watts, II. 199). 5. Hydrocyanic acid and the soluble cyanides, except mercuric cyanide, precipitate the white silver cyanide from solutions of **silver salts**; the precipitate forms soluble double compounds with the alkali cyanides. 6. They decompose **mercurous compounds**, forming metallic mercury and mercuric salts. In case of **calomel** the powder is turned dark at once on account of the metallic mercury. 7. The alkali cyanides precipitate solutions of **lead salts** as white lead cyanide. 8. The alkali cyanides precipitate solutions of **copper salts** as the yellow-green copper cyanide, which is soluble in excess of the alkali cyanide. 9. Potassium cyanide with a solution of **ferrous sulphate** gives a brown precipitate of ferrous cyanide which dissolves in excess of the alkali cyanide forming potassium ferrocyanide. 10. **Nitric acid** decomposes cyanides with the evolution of nitrogen and other gases (N. S. D., 55). 11. Cyanides reduce **potassium permanganate** and are changed to carbon dioxide, nitric, nitrous, oxalic, and formic acids (M. & M., II.

346). 12. **Chlorine** or **chlorinated lime** with a solution of potassium cyanide forms chloride of cyanogen and hydrochloric acid (M. & M., II. 302). 13. With a concentrated solution of **iodine** potassium cyanide forms potassium iodide and iodide of cyanogen (M. & M., II. 342). Even in dilute solutions the color of iodine is destroyed. 14. Rubbed with **potassium nitrate** or **chlorate**, potassium cyanide detonates violently. 15. If potassium cyanide and **chloral hydrate** are rubbed together reaction takes place with the evolution of a large volume of white fumes. 16. Aqueous solutions of the alkali cyanides being alkaline may precipitate **alkaloids** from solutions of their salts as the free alkaloids. 17. Cyanides of the alkalies and alkaline earths are decomposed by all **acids**, even carbonic, with the liberation of hydrocyanic acid. 18. The cyanides of the alkalies and the alkaline earths and mercuric cyanide are soluble in water; the others are made soluble in the presence of the alkali cyanides by forming double compounds. Excepting mercuric cyanide they are generally insoluble in alcohol. 19. **Atropine** and **ammonia** are physiologically antagonistic to cyanides in that they quicken the heart beat.

**Acidum Hypophosphorosum Dilutum.**—1. Dilute hypophosphorous acid is oxidized to phosphorous and phosphoric acids on exposure to **air**. 2. Hypophosphorous acid and hypophosphites in acid solution are oxidized to phosphoric acid by nearly all **oxidizing agents**, and cause a reduction of these agents. 3. **Nitrous** or **nitric acid** forms nitric oxide. 4. **Sulphurous acid** forms sulphur. 5. **Chlorine** and **chlorates** are changed to hydrochloric acid or chlorides. 6. **Iodine** is reduced to hydriodic acid. 7. **Mercurous** and **mercuric compounds** are reduced to the metal, even in neutral and alkaline mixtures. **Calomel** is turned dark at once when mixed with potassium hypophosphite. 8. **Permanganates** are changed to manganous compounds (to manganese dioxide in alkaline mixtures). 9. **Chromates** form chromic salts. 10. **Cupric sulphate** with hypophosphorous acid gives a precipitate of cuprous hydride which begins to form after an hour or more. Copper sulphate with

potassium hypophosphite gives a white precipitate. 11. **Bismuth subnitrate** with potassium hypophosphite in the presence of moisture becomes brown or black after some time, much more quickly in the presence of an acid. Bismuth is reduced to metallic bismuth (P. & J., 296). 12. In the presence of hydrochloric acid **arsenic acid** is reduced to arsenous acid and then to metallic arsenic (P. & J., 296). 13. **Ferric salts** are reduced to ferrous in acid mixture (P. & J., 296). When an alkali hypophosphite is added to a solution of ferric chloride a white precipitate of ferric hypophosphite is formed which is dissolved by adding a large excess of hydrochloric acid or an alkali citrate in considerable amount. 14. Compounds of **silver** and **gold** are reduced to the metals. 15. Hypophosphorous acid dissolves **quinine sulphate** with a blue fluorescence. Adding potassium hypophosphite to the solution destroys the fluorescence and in sufficient amount precipitates the quinine. 16. Hypophosphites are decomposed by nearly all **acids**. 17. Hypophosphites when triturated with some **oxidizing agents**, as potassium chlorate, are apt to cause an explosion. 18. Hypophosphites are soluble in water, except ferric hypophosphite which is only sparingly soluble. Many are soluble in alcohol. [See ACIDA.]

**Acidum Lacticum.**—1. Lactic acid displaces acetic and carbonic acids from their compounds. 2. It coagulates a solution of **albumin**. 3. With **nitric acid** it forms **oxalic acid** (N. S. D., 59). 4. With **potassium permanganate** and sulphuric acid it gives the odor of aldehyde (U. S. P., 17). With potassium permanganate it gives pyruvic acid (M. & M., III. 110). Oxidized with potassium permanganate it yields pyroracemic acid (Richter, I. 336). 5. **Hydriodic acid** at once reduces lactic acid to propionic acid (Richter, I. 336). 6. Lactates are generally insoluble in water and alcohol. [See ACIDA.]

**Acidum Meconicum.**—1. Meconic acid, with a nearly neutral solution of a **ferric salt**, gives a red-colored solution, the color being destroyed by large excess of hydrochloric acid.

2. It gives a white precipitate with solutions of **lead acetate**, **silver nitrate**, **barium chloride**, and **calcium chloride** (U. S. D., 902).

**Acidum Nitricum.**—1. Nitric acid is a strong oxidizing agent, and in oxidizing substances it is reduced to dinitrogen tetroxide ( $N_2O_4$ ), nitrous anhydride ( $N_2O_3$ ), nitric oxide (NO), nitrous oxide ( $N_2O$ ), nitrogen, or ammonia. 2. Nitric acid oxidizes **hypophosphites** to phosphates; 3. **sulphides** to sulphur, and then sulphates; 4. **sulphites** to sulphates; 5. **bromides** to free bromine; 6. **iodides** to free iodine, and then to iodic acid; 7. **oxalates** to carbon dioxide; 8. **citrates** to acetic and oxalic acids and carbon dioxide; 9. **mercurous compounds** to mercuric; 10. **arsenous compounds** to arsenic; 11. **ferrous compounds** to ferric. 12. Nitric acid dissolves many **metals**, while it itself is partly decomposed. 13. With concentrated **hydrochloric acid** it forms chlorine and oxychlorides of nitrogen. 14. With **carbolic acid** it forms picric acid. 15. Nitric acid reacts with **tannic acid**, giving off oxides of nitrogen. 16. With **salicylic acid** it forms nitrosalicylic acid. 17. With **alcohol** it acts violently, giving off red fumes, and forming aldehyde, acetic, formic, and carbonic acids. 18. With **creosote**, **volatile oils**, and other **organic substances** the reaction with nitric acid may be so violent as to cause explosion or ignition. 19. Nitric acid gives color reactions with many of the alkaloids. **Apo-morphine** with nitric acid gives a violet-red; 20. **brucine** a scarlet to blood-red; 21. **physostigmine**, a yellow or red; 22. **berberine**, a dark brown-red; 23. **codeine**, a yellow; 24. **hydrastine**, an orange; 25. **morphine**, an orange-red, changing to yellow. 26. Nitric acid gives a red color with **barbaloin** and **nataloin**, but not with **socaloin**. 27. Nitric acid replaces many weak acids, such as carbonic, acetic, and boric acids, when they are combined with bases. 28. Nitric acid with concentrated sulphuric acid and **glycerin** forms the explosive nitroglycerin. 29. With sulphuric acid and **cotton** or other **cellulose** it forms gun-cotton, some of the com-

pounds being explosive. 30. Nitric acid with **sugar** and heat forms oxalic acid. Very concentrated nitric acid in the cold with sugar forms an explosive compound. Dilute nitric acid oxidizes sugar to saccharic acid, while very dilute acid changes it to glucose. 31. Nitric acid with **silver** or **mercuric nitrates**, and **strong alcohol** forms the explosive fulminate of silver or mercury. 32. Dilute nitric acid, while an oxidizing agent, is not as active as the concentrated. It may not give color reactions with some of the alkaloids. 33. Fuming nitric acid is a more active oxidizing agent than the concentrated acid. When it is mixed with **organic matter**, violent explosion or ignition is liable to take place. 34. Nitrates with **sulphuric acid** give nitric acid. 35. Nitrates, particularly those of the fixed alkalies, when triturated with substances capable of being readily oxidized, are liable to explode; some of these substances are **charcoal**, **phosphorus**, **sulphur**, **sugar**, **sulphides**, **potassium cyanide**, **glycerin**, **alcohol**, and **oils**. 36. The nitrates are all soluble in water; the basic nitrates of bismuth and of mercury are insoluble. Most of the nitrates are nearly or quite insoluble in alcohol. [See ACIDA.]

**Acidum Nitrohydrochloricum.**—1. Unless very highly diluted, nitrohydrochloric acid gives a yellow coloration with **strychnine sulphate**. The products formed have not been determined. 2. Nitrohydrochloric acid is a very strong oxidizing agent, and is liable to cause violent reaction when mixed with **organic matter**. 3. It has the oxidizing properties of chlorine and the precipitating properties of hydrochloric acid. [See CHLORUM and ACIDUM HYDROCHLORICUM.]

**Acidum Nitrosum.**—1. Nitrous acid and acid solutions of nitrites, such as potassium or sodium nitrite, amyl nitrite or ethyl nitrite (in spirit of nitrous ether), all act in a similar manner. Sometimes they act as oxidizing and sometimes as reducing agents. In neutral or alkaline mixtures nitrites do not generally oxidize or reduce. 2. The spirit of

nitrous ether readily undergoes decomposition, forming alcohol, aldehyde, acetic acid, nitrous acid, nitric acid, and other products. Water tends to hasten and absolute alcohol prevent decomposition. 3. Ethyl nitrite in the spirit of nitrous ether is decomposed by **alkali hydroxides**, forming alcohol and a nitrite of the alkali. Aldehyde is often present and the alkali gives a yellow to a brown color with this. 4. **Hypophosphites** form phosphoric acid and nitric oxide when mixed with acid solutions of nitrites. 5. **Sulphites** form sulphates and nitric oxide. 6. **Chlorates** form peroxide of chlorine, then hydrochloric and nitric acids. 7. **Iodides** form iodine and nitric oxide. 8. **Ammonium bromide** is decomposed by spirit of nitrous ether, liberating bromine. The other bromides are not readily affected. 9. **Mercurous salts** are reduced to metallic mercury. 10. Spirit of nitrous ether after standing with a solution of mercuric chloride causes the formation of a white precipitate which responds to the tests of calomel. 11. **Permanganates** are reduced to manganous salts and nitric acid is formed. 12. **Chromates** are reduced to chromic salts. 13. **Gold chloride** is reduced to metallic gold. 14. **Hydrogen dioxide** oxidizes nitrous acid to nitric. 15. Nitrites with **sulphuric acid** and **alcohol** form ethyl nitrite. 16. Nitrous acid changes **oleic acid** to the isomeric form elaidin. 17. **Antipyrine** with acid solutions of nitrites gives the green isonitroso-antipyrine. [See ANTIPYRINA, No. 17.] 18. **Acetanilide** gives a yellow color with acidulated solutions of nitrites. [See ACETANILIDUM, No. 1.] 19. Spirit of nitrous ether with **sodium salicylate** gives a brown-red color if allowed to stand for a day or two. 20. **Phenacetin** slowly gives a yellow color which deepens. 21. **Piperazin** gives a yellow to a red solution, with spirit of nitrous ether. 22. **Carbolic acid** with spirit of nitrous ether and water gives a yellow solution at once which begins to assume a red-brown color in five minutes and in one half hour is a deep red brown. In a few hours it becomes turbid and deposits a solid. 23. With **tannic** or **gallic acid** or preparations containing them in large amounts, nitrites in acid solution (as an old spirit of nitrous

ether) give off gaseous compounds, consisting chiefly of oxides of nitrogen. The reaction may continue for some time, and bottles containing the mixture should not be stoppered until reaction has ceased. 24. With **thymol** spirit of nitrous ether gives a green and then a brown color, changing the thymol to nitroso-thymol. 25. Spirit of nitrous ether produces a yellow color with **morphine**. Morphine is converted into nitroso-morphine, pseudomorphine, and another base (M. & M., III. 436). 26. It gives a red color with aloin. 27. Spirit of nitrous ether with a tincture of **guaiaac** gives a blue color which changes to deep red in a few minutes. If the guaiaac has been exposed to the light and air for some time the blue color is not produced. 28. Spirit of nitrous ether converts **acetates** into carbon monoxide, and other gases (Scoville, 283). An effervescence is frequently quite noticeable. 29. Nitrites are quite soluble in water, except silver, which is only sparingly soluble. [See ACIDA.]

**Acidum Oleicum.**—1. Oleic acid combines with **alkalies** to form soaps. 2. **Nitric acid** oxidizes oleic acid to acetic, propionic, butyric, valeric, adipic, azelaic, and other acids (M. & M., III. 637). 3. **Nitric acid** containing **nitrous acid fumes** or **nitrous acid** converts oleic acid into the isomeric elaidic acid, which is solid. 4. **Potassium permanganate** in alkaline mixtures gives azelaic acid and dioxystearic acids (M. & M., III. 637). 5. Concentrated **sulphuric acid** yields oxystearic acid. 6. **Bromine** and **iodine** combine with oleic acid to form addition products. [See ACIDA.]

**Acidum Phosphoricum.**—1. Free orthophosphoric acid partially precipitates solutions of **silver nitrate** and **lead acetate**. 2. With a solution of **ferric chloride** it forms the colorless ferric phosphate, which is kept in solution by the liberated hydrochloric acid. Tannic acid or preparations containing it do not give the black color when added to this solution of ferric phosphate. 3. Orthophosphoric acid does not coagulate egg **albumin** or **gelatin** (difference from metaphosphoric acid). 4. Phosphoric acid when added to a solution of **soluble phosphate** or **soluble pyrophosphate** of iron

produces a white precipitate of ferric phosphate or of pyrophosphate of iron. A large excess of the free acid redissolves the precipitate. 5. The alkali phosphates precipitate neutral solutions of nearly all other common **metals**. The precipitate is a di- or tri-metallic phosphate, and excepting lead, mercurous, antimony, and bismuth phosphates, is generally dissolved by phosphoric acid forming mono-metallic salts. 6. The official sodium phosphate is frequently slightly alkaline and in that condition is apt to precipitate **alkaloids** from solutions of their salts. 7. **Acetic acid** transposes most of the insoluble phosphates, except those of iron, aluminum, and lead. Dilute **nitric, hydrochloric, and sulphuric acids** transpose all phosphates. 8. A soft mass is produced when the official sodium phosphate is triturated with quite a number of solids. [See page 267.] 9. The di- and tri-metallic phosphates, except those of the alkalies, are insoluble in water, but many are soluble in a solution of an alkali citrate or an acid. The mono-metallic phosphates are soluble in water to some extent. Phosphates are insoluble in alcohol.

10. Metaphosphoric acid precipitates solutions of **silver nitrate**, and **lead acetate**, and **ferric chloride** salts of barium and calcium (difference from orthophosphoric acid). 11. It does not cause a precipitation when it is added to a solution of the **soluble phosphate** or **pyrophosphate of iron**. 12. It coagulates solutions of **egg albumin** or **gelatin**. 13. In aqueous solutions metaphosphoric acid slowly changes to orthophosphoric acid.

14. Pyrophosphoric acid precipitates solutions of **lead acetate, ferric chloride, and gelatin**. 15. The pyrophosphates of the alkalies are soluble in water, and precipitate solutions of salts of nearly all other **metals**. 16. Most of the pyrophosphates are soluble in solutions of alkali pyrophosphates as double salts. Alkali citrates also have a solvent effect. [See ACIDA.]

**Acidum Picricum.**—1. Picric acid and picrates precipitate **albumin, gelatin, and most alkaloids** from aqueous

solutions of their salts. 2. Salts of picric acid explode when struck or strongly heated (Richter, II. 151). 3. It is explosive when rubbed or heated with readily oxidizable substances such as sulphur. [See ACIDA.]

**Acidum Salicylicum.**—1. Salicylic acid unites with **alkali hydroxides** and with many **metallic oxides** to form salts. 2. Salicylic acid liberates carbon dioxide from **carbonates**. 3. Solutions of the salicylates in water, particularly if alkaline, become colored red brown on exposure to the **air**. This can be prevented by the addition of a small proportion of sodium thiosulphate. 4. Sodium salicylate precipitates solutions of **lead acetate** and **silver nitrate** as salicylates. 5. Salicylic acid and soluble salicylates with dilute solutions of **ferric salts** give a blue-violet to a violet-red color, depending upon the concentration. In rather acid solutions the color varies from that of the iron to brown or red. The color is destroyed by a large excess of a mineral acid or acetic acid. In nearly neutral solutions a precipitate of basic ferric salicylate is formed. 6. Sodium salicylate with **copper sulphate** gives a green solution from which the copper is not precipitated in dilute solutions by alkali hydroxides. 7. **Lime water** gives a precipitate when mixed with a concentrated solution of sodium salicylate. 8. With **bismuth subnitrate** sodium salicylate in aqueous solution is said to give several compounds of bismuth and salicylic acid which have a color varying from white to red orange. The coloration, according to the author's experience, is not noticeable except after the lapse of considerable time, and may then be due to oxidation products of salicylic acid. 9. A solution of **potassium iodide** with salicylic acid becomes yellow in one day, and after a few days it is brown and gives a test for iodine. 10. Concentrated **nitric acid** with salicylic acid gives nitrosalicylic acid. 11. **Potassium chlorate** with hydrochloric acid converts salicylic acid into tetrachloroquinone (N. S. D., 76). **Chlorine** forms mono- and di-chloro-salicylic acid (M. & M., III. 680). 12. A solution of **iodine** is slowly decolorized by sodium salicylate. Iodine gives mono-, di-, and tri-iodo-salicylic acid and tri-iodo-phenol (M. & M., III. 680).

13. **Bromine water** gives a precipitate with dilute solutions of salicylates. 14. **Potassium permanganate** oxidizes salicylic acid to formic acid and carbon dioxide. 15. Sodium salicylate with **spirit of nitrous ether** gives a yellow solution which changes to red brown in a few hours. 16. A mixture varying from a damp powder to a liquid results when salicylic acid or sodium salicylate is rubbed with **exalgine**, **lead acetate**, **sodium phosphate**, or **urethane**. In case of lead acetate there is a strong odor of acetic acid, indicating that acetic acid is liberated. 17. Salicylic acid is said to give a soft mass when it is rubbed with **antipyrine**, but according to the author's experiments this is not the case. 18. Sodium salicylate rubbed with **antipyrine** gives a powder which becomes damp and sticky. Some say that this is due to absorption of moisture from the air, while others say that chemical reaction takes place. 19. Soluble salicylates with solutions of **quinine sulphate** give a white curdy precipitate of quinine salicylate which is nearly insoluble in water. Sodium salicylate with a dilute solution (1:1000) of quinine sulphate gives a crystalline precipitate in a few days. 20. **Mineral acids** and some **organic acids** liberate salicylic acid from solutions of the salicylates. Salicylic acid, being but slightly soluble, is precipitated from a not too dilute aqueous solution. 21. A concentrated aqueous solution of sodium salicylate (1:1) is a good solvent for **volatile oils**, **resinous substances**, **carbolic acid**, **guaiacol**, **creosote**, **thymol**, **menthol**, and other bodies. More or less water can be added to these solutions without precipitation. 22. Sodium salicylate tends to prevent precipitation of some of the metallic oxides or hydroxides. 23. Salicylic acid is rendered more soluble in water by the presence of **borax**. The compound  $C_{14}H_{10}NaBO_7$  is said to be formed and deposited in the form of crystals from strong solutions, and also that the liquid soon undergoes decomposition, acquiring a bitter taste (N. S. D., 75). 24. Salicylic acid is rendered more soluble in water by the presence of several neutral salts, such as the citrates, acetates, and phosphates of the

alkalies, by potassium nitrate, and by sodium sulphite. [See ACIDA.]

**Acidum Stearicum.**—1. Stearic acid combines with the **alkali hydroxides** and **carbonates** to form stearates. 2. **Nitric acid** oxidizes it to succinic and other acids (M. & M., IV. 512). 3. **Bromine water** forms mono- and di-bromostearic acid (M. & M., IV. 513).

**Acidum Sulphuricum.**—1. Sulphuric acid transposes the **salts** of nearly all other acids. 2. Sulphuric acid and the soluble sulphates precipitate as sulphates solutions of salts of **lead, barium, calcium** (in concentrated solution), and **strontium**. The addition of potassium tartrate dissolves some of the precipitates. 3. Sulphuric acid dissolves many **metals** with the evolution of hydrogen or sulphur dioxide, depending on the concentration of the acid. 4. With **hypophosphorous acid** it forms sulphurous acid and then sulphur. 5. **Hydriodic acid** with concentrated sulphuric acid forms iodine and sulphurous acid. Dilute acid liberates hydriodic acid from iodides. 6. Concentrated sulphuric acid causes detonation with **chlorates**, with the evolution of the greenish-yellow chlorine peroxide. 7. With **alcohol** sulphuric acid forms ethylsulphuric acid and then ether. 8. **Water** precipitates the aromatics from the aromatic sulphuric acid. 9. The concentrated acid with most **organic matter** forms a black mass, due to the extraction of the elements of water, leaving carbon. Some organic acids, many alkaloids, and some other compounds are not thus affected. 10. Dilute sulphuric acid does not cause as many decompositions as the concentrated. 11. The sulphates of lead, barium, strontium, and calcium are nearly insoluble in water; silver and mercurous sulphates are sparingly soluble; mercuric, antimony, and bismuth are soluble in acidulated water; the others are soluble in water. Sulphates are generally insoluble in alcohol. [See ACIDA.]

**Acidum Sulphurosum.**—1. Sulphurous acid on exposure to **air** is slowly oxidized to sulphuric acid. 2. Sulphurous acid does not usually precipitate solutions of metallic

salts. The soluble sulphites—potassium, sodium, and ammonium—precipitate neutral solutions of salts of nearly all other **metals**. Sometimes sulphurous acid contains sulphuric acid which may cause reaction in certain cases. 3. Sulphites and sulphurous acid give a red color with a dilute solution of **ferric chloride**. The color is soon destroyed, due to the change of the ferric sulphite to ferrous sulphate. 4. **Nitric** or **nitrous acid** oxidizes sulphites to sulphates. 5. **Hypophosphites** in acid solution with sulphites form phosphoric acid and sulphur. 6. Sulphites with **chlorine**, or **chlorates** in acid solution, produce sulphuric and hydrochloric acids. 7. **Silver salts** in solution are first precipitated by sulphites and then reduced to metallic silver when warmed. 8. **Arsenic compounds** are reduced to arsenous. 9. **Permanganates** in acid solution are reduced by sulphites to manganous compounds. 10. **Chromates** in acid solution are reduced to chromic salts. 11. **Mercuric** and **mercurous nitrates** are reduced to metallic mercury. **Mercuric chloride** is slowly reduced to calomel and on heating to metallic mercury; the sulphurous acid acts more quickly than the sulphites. 12. Sulphurous acid has a bleaching effect on organic **coloring matters**. 13. Sulphites are decomposed by nearly all **acids**, except carbonic, boracic, hydrocyanic, and in some instances hydrosulphuric. 14. The sulphites of the alkali metals are soluble in water; the sulphites of the alkaline earths are soluble in sulphurous acid; the others are insoluble or sparingly so. The sulphites are insoluble in alcohol. [See ACIDA.]

**Acidum Tannicum.**—1. An aqueous solution of tannic acid changes, forming gallic acid and probably some elagic and carbonic acids. The change is retarded or prevented by the presence of glycerin or alcohol (Caspari, 718). The solution gets darker on standing and this is hastened by alkalis. 2. Tannic acid in dilute solutions combines with the **alkali hydroxides** and **carbonates** to form soluble tannates and these solutions soon become colored, varying from red to brown, green, or black. 3.

**Potassium hydroxide** or **carbonate** with a concentrated solution of tannic acid gives a compound which is but slightly soluble in water, but dissolves in a certain excess of alkali (U. S. D., 81). When potassium hydroxide is added in excess to a solution of tannic acid, tannoxyllic acid or rubitannic acid is formed; if the mixture is boiled tannomelanin acid is formed (A. D., 95). 4. **Ammonia** in its reactions resembles potassium hydroxide (U. S. D., 81) but the precipitate is not nearly so great unless ammonium chloride has been previously added to the ammonia. 5. **Sodium hydroxide** gives little or no precipitate. 6. A small amount of **lime water** added to a solution of tannic acid gives a precipitate which redissolves; adding more lime water the precipitate is white and permanent, changing to light blue and then dark blue as more lime water is added; a very large excess of lime water gives a precipitate which is pinkish. 7. Tannic acid precipitates as tannates solutions of salts of many of the metals, especially **lead**, **silver**, **mercury**, **copper**, **bismuth**, and **antimony**. 8. The alkali tannates give precipitates with solutions of salts of nearly all other **metals**. 9. With solutions of **ferric salts** tannic acid gives a solution or precipitate (depending on the concentration) of a dark blue-black to green-black color. The addition of enough of phosphoric acid to convert the iron into ferric phosphate prevents or destroys the color. Theoretically forty-eight minims of 10 per cent. phosphoric acid is sufficient to convert one dram of the official tincture of ferric chloride into the phosphate. Practically it requires from one and a half to two times as much dilute acid as tincture, depending to some extent upon the amount of tannic acid, to prevent the formation of the dark tannate of iron. 10. With purely **ferrous salts** in concentrated solution (not in dilute solution) it gives a white gelatinous precipitate, which quickly becomes blue on exposure to air. Nearly all commercial samples of ferrous sulphate contain some ferric salt. 11. A strong solution of tannic acid gives precipitates with concentrated **sulphuric**, **hydrochloric**, or **phosphoric acids**. These precipitates are

supposed to be compounds of tannic acid with the respective acids, and are soluble in pure water but not in acidulated water (U. S. D., 81). 12. Saturated solutions of **sodium chloride**, **calcium chloride**, **potassium acetate**, and some other **salts** precipitate tannic acid from strong solutions. Precipitated by mineral salts or acids, tannic acid loses its astringency (Br. P., 21). 13. **Potassium bichromate** gives precipitates with most tannins (M. & M., IV. 634). 14. **Potassium cyanide** gives a green coloration with a solution of tannic acid (M. & M., IV. 634). 15. With tannic acid and water **iodine** forms hydriodic acid, which combines with part of the tannic acid and remains in solution; the oxygen of the decomposed water combines with tannic acid and forms an insoluble compound; the solution is capable of dissolving iodine; the iodine in a liquid containing an excess of tannic acid does not give a blue color with starch (U. S. D., 81). 16. **Nitric acid**, **chromic acid**, **chlorine**, or **bromine** oxidizes tannic acid to formic and oxalic acids (A. D., 95). 17. Tannic acid reduces **potassium permanganate**. 18. Tannic acid with **Fowler's solution** or a solution of **sodium arsenate** gives a nearly white precipitate which with the liquid turns to a dark dirty green within a day. 19. **Hydrogen dioxide water** with tannic acid shows no change at first but after a few days a light brown precipitate falls. 20. Tannic acid reduces salts of **gold**, **silver**, **mercury**, and **copper** (Allen, III. part I. 35). 21. Triturated with **potassium chlorate** or other substances which yield their oxygen readily, tannic acid is liable to cause an explosion. 22. With **spirit of nitrous ether**, **amyl nitrite**, or **nitrous acid** tannic acid causes a decomposition and the formation of gaseous compounds some of which are oxides of nitrogen. The solution becomes deep red. 23. Tannic acid gives precipitates with solutions of **albumin**, **gelatin**, **glutin**, or **starch**. 24. It precipitates as tannates nearly all **alkaloids** from aqueous or dilute alcoholic solutions of their salts; the precipitate is generally soluble in mixtures containing over

fifteen to forty per cent. alcohol. The presence of some organic acids, acacia, or starch also tends to prevent the precipitation. 25. Tannic acid precipitates some **glucosides**, **neutral** and **bitter principles**. 26. It precipitates aqueous solutions of **antipyrine**. 27. Tannic acid slowly decomposes **iodoform** (U. S. D., 662). 28. All drugs containing tannic acid in large proportions will have the incompatibilities given above. Some of the drugs which contain notable quantities of tannic acid are catechu, kino, krameria, logwood, geranium, blackberry-root bark and oak bark. [See ACIDA.]

**Acidum Tartaricum.**—1. When tartaric acid is added in excess to a rather strong solution of **potassium hydroxide** or many of its salts, a crystalline precipitate of potassium bitartrate forms. 2. When tartaric acid is associated with **boric acid** it is not precipitated by potassium hydroxide, even on adding acetic or hydrochloric acid (U. S. D., 84). Boric acid seems to act the part of a base with tartaric acid (Watts, 1. 648). 3. Tartaric acid in excess with a strong solution of **ammonia** gives a precipitate of ammonium bitartrate. 4. Potassium tartrate or Rochelle salt gives a precipitate of potassium bitartrate on adding many **acids**, the precipitate dissolving in a large excess of a mineral acid. 5. The soluble tartrates precipitate as tartrates neutral solutions of salts of most **metals**. The precipitate is generally soluble in tartaric acid or mineral acids. Many of the tartrates form soluble compounds with the alkali hydroxides, due to the formation of double tartrates. 6. Tartaric acid decomposes **potassium iodide**, forming a tartrate and hydriodic acid which is slowly decomposed by the air, liberating iodine. 7. Under certain conditions tartrates reduce salts of **gold**, **silver**, and **platinum**; **mercuric chloride** becomes mercurous chloride. 8. **Potassium permanganate** with an alkaline solution of a tartrate is reduced to manganese dioxide, while the tartaric acid is converted into formic acid, carbon dioxide, and water; free tartaric acid is acted upon but slowly. 9. **Chromates** oxidize tartaric acid to formic acid, carbon dioxide, and water (M. & M., iv. 642). 10. Tartaric acid and tartrates tend to

prevent the precipitation by alkali hydroxides of the oxides and hydroxides of the **metals** aluminum, antimony, bismuth, nickel, calcium, cobalt, chromium, copper, iron, lead, and zinc. 11. Tartrates in aqueous solutions have more or less solvent effect on certain salts which ordinarily are insoluble, as calcium phosphate, lead sulphate, and barium sulphate. 12. Tartrates are transposed by mineral **acids**. 13. Tartrates of the alkali bases are soluble in water. The bitartrates of potassium and ammonium are sparingly soluble. The manganous and ferric tartrates are soluble; calcium tartrate, sparingly soluble. The other tartrates are nearly insoluble. Tartrates are generally insoluble in alcohol. [See ACIDA.]

**Acidum Trichloraceticum.**—1. Trichloracetic acid precipitates solutions of **albumin**. 2. It is decomposed when heated with **alkalies** and **carbonates**, forming carbon dioxide and chloroform (N. S. D., 92).

**Aconitina.**—1. Aqueous solutions of salts of aconitine are precipitated by **alkali hydroxides**, the **carbonates** of the fixed alkalies, and by the **general alkaloidal reagents**, but not by ammonium carbonate or the bicarbonates. 2. Aconitine is decomposed by long standing or by heating with **acids**, **alkalies**, or **water**, forming benzoic acid, acetic acid, and aconine. 3. **Nitric acid** gives a red-brown solution. [See under ALKALOIDS.]

**Adeps.**—1. Lard oxidizes on exposure to **air** and **light**, becoming acid and rancid, and in this condition liberates iodine from potassium iodide. 2. Lard is decomposed by **alkali hydroxides** or **carbonates**, forming glycerin, and oleates, stearates, and palmitates of the alkalies. Commercial lard sometimes contains alkalies or alkaline carbonates in small amounts, and consequently has the incompatibilities of these. [See ACIDUM OLEICUM and ACIDUM STEARICUM.]

**Adrenalin.**—1. Adrenalin is weakly alkaline and forms salts with **acids**. 2. Strong **alkalies** will precipitate adrenalin from solutions of its salts (Bul. Pharm., xvii. 478). 3. Adrenalin is not precipitated by the **alkaloidal reagents** unless it is hydro-

lized by heating in an autoclave or treating with strong hydrochloric acid, when it then assumes the properties of an alkaloid (N. S. D., 107). 4. Exposure to **air** destroys its action (Bul. Pharm., xvii. 478). 5. **Ferric chloride** gives an emerald green color, changing to brown (N. S. D., 107). 6. **Iodine** gives a vivid pink (N. S. D., 107). 7. **Oxidizing agents** like gold chloride, silver nitrate, nitric acid, or potassium dichromate, are reduced, the adrenalin is rendered inert (Bul. Pharm., xvii. 478) and the liquid is colored pink to red (N. S. D., 107).

**Æther.**—1. In partly filled bottles, particularly in the presence of **water**, ether becomes acid, due to the formation of acetic acid. 2. Ether in the light is said to tend to produce hydrogen dioxide (M. R. xviii, 228). 3. After a few days ether with **bromine** forms ethyl bromide, bromal, and other products. 3. Hot **nitric acid** forms carbon dioxide, acetic and oxalic acids. 4. **Chromic acid** oxidizes it to acetic acid (M. & M., ii. 465).

**Æther Aceticus.**—1. Ethyl acetate in the presence of **moisture** decomposes into alcohol and acetic acid. 2. With **alkaline hydroxides** it yields alcohol and an acetate of the alkali. 3. It forms chlorinated compounds with **chlorine**. 4. With **lime water** and **chlorinated lime** it yields chloroform.

**Æthyleni Bichloridum.**—1. Dichlorethane with water in the **sunlight** yields hydrochloric acid and acetic acid. 2. **Ammonia water** forms various ethylene amines (M. & M., ii. 488).

**Æthylis Bromidum.**—1. Ethyl bromide is decomposed by light and air, forming alcohol, hydrobromic acid, and some free bromine. The presence of one per cent. of alcohol or three per cent. of ether makes it more stable (N. S. D., 115). 2. With **alkali hydrates** it gives ether and potassium bromide (M. & M., 480). 3. Ethyl bromide with **ammonia** gives hydrobromate of ethylamine (Watts, ii. 528).

**Æthylis Carbamas, Urethane.**—1. Urethane in the presence of **iodine** and an **alkali hydroxide** or **carbonate** produces iodoform. 2. Warming it with a solution of **potassium hydroxide** causes ammonia to be given off (U. S. P., 32).

With an alcoholic solution of potassium hydroxide it gives large crystals of potassium cyanate (M. & M., I. 679). 3. When rubbed with **benzoic acid** or some other solids urethane gives a liquid or soft mass. [See page 267.]

**Æthylis Iodidum.**—1. Ethyl iodide or hydriodic ether on being exposed to **air** and **light** is decomposed with liberation of iodine (N. S. D., 119). 2. Iodine is liberated by **chlorine**, **nitric acid**, and **sulphuric acid**. 3. Silver nitrate gives precipitate of silver iodide (M. & M., II. 499).

**Agurin, Theobromine-sodium and sodium acetate.**—1. Agurin is readily soluble in water but not in alcohol. The solution is strongly alkaline and the alkalinity causes many incompatibilities. 2. Adding dilute **acids** to not too dilute solutions of agurin gives a precipitate at once or on standing and the precipitate is probably theobromine. 3. In the presence of **air** and **moisture** it absorbs carbon dioxide and is decomposed and precipitated. 4. A solution of **ferric chloride** with an excess of agurin gives a red-brown precipitate. 5. With solutions of **mercuric chloride**, **lead acetate**, **tartar emetic**, **magnesium sulphate** it may give a precipitate at once or on standing. 6. An aqueous solution darkens **calomel** at once. 7. It reduces **potassium permanganate** to some extent. 8. A dilute aqueous solution gives a gelatinous precipitate with **silver nitrate** but the silver is not reduced on standing for several hours. 9. Excess of tincture of **iodine** causes little or no precipitation at once when added to a solution of agurin, but if the agurin is in excess the iodine is decolorized and a yellowish, gelatinous mass or thick liquid results, which slowly becomes thin again and deposits a white precipitate. 10. It precipitates many **alkaloids** from solutions of their salts. 11. Rubbed with **chloral hydrate**, **carbolic acid**, or **piperazine** it gives a mass.

**Airol, Bismuth Oxyiodogallate.**—1. **Moist air** causes the powder to become red (N. S. D., 311). Mixed with **water** airol partially decomposes and turns red. Glycerin tends to prevent this. 2. It is soluble in solutions of **acids** and **alkalies** with decomposition and change of color (N. S. D., 311). 3. With

**calomel** it tends to form mercuric iodide (D. C., XLVII. 43).

4. No **metallic** instruments should come in contact with it as they may liberate iodine (U. S. D., 1373).

**Albumin.**—1. The coagulability of the different albumins varies. 2. Aqueous solutions of egg albumin are precipitated by **heat** and by many **mineral acids**, as **hydrochloric**, **nitric**, and **meta-phosphoric** (not by ortho- or pyro-phosphoric acid); 3. by salts of many heavy metals, as **mercuric chloride** (prevented to a considerable extent by the presence of ammonium or sodium chloride or hydrochloric acid), **alum**, **copper sulphate**, **silver nitrate**, **gold chloride**, and **ferric chloride**; 4. by some neutral salts, as **ammonium sulphate**; 5. by **hydrogen dioxide water**; 6. by some organic acids, as **tannic acid** and substances containing it (not by gallic acid), **lactic acid**, **picric acid**, **carbolic acid**, **creosote**, **acetic** and **trichloroacetic acids**; 7. by some organic compounds, as **alcohol** (the precipitate is redissolved by dilution with water if the albumin has not been in contact with the alcohol too long), **formaldehyde**, **ether**, **collodion**, **resorcin**, **camphor**, **thymol**, **sozoidol**, **volatile oils**, and **coniine** (not nicotine).

**Alcohol.**—1. Alcohol precipitates **albumin**, **acacia**, and many **inorganic salts** from their aqueous solutions; to precipitate the acacia the resulting mixture must contain about thirty or forty per cent. alcohol before a permanent precipitate results. 2. Strong **nitric acid** (not dilute) acts violently on alcohol, forming nitric oxide, nitrous ether, carbon dioxide, aldehyde, acetic and formic acids (M. & M., I. 97). 3. **Chromic acid** or a **chromate** in an acid solution oxidizes alcohol to aldehyde and acetic acid. 4. **Potassium permanganate** in acid (not in alkaline) solution oxidizes it to aldehyde and acetic acid. 5. **Chlorine** is rapidly absorbed by alcohol and in sunlight may ignite the alcohol. The ultimate product is chloral alcoholate, there being a number of intermediate products, such as hydrochloric acid, aldehyde, ethyl chloride, acetic acid, chloral, etc. (M. & M., I. 97). 6. **Bromine** forms hydrobromic acid, water, ethyl bromide,

bromal, and bromal alcoholate (M. & M., I. 97). 7. **Mercuric chloride** is slowly reduced to calomel by alcohol (M. & M., I. 98). 8. **Nitric acid** with the nitrate of **mercury** or **silver** and strong alcohol forms the explosive fulminate of mercury or silver (M. & M., I. 97). 9. Concentrated **mineral acids** convert alcohol into esters and ethers. 10. Alcohol combines with many **metallic salts**, acting like water of crystallization (M. & M., I. 98). 11. With **chloral hydrate** alcohol forms chloral alcoholate which is not very soluble in elixir and less so in the presence of potassium bromide. 12. Alcohol sometimes contains traces of aldehyde or other impurities which are darkened by **alkali hydroxides**. 13. The official alcoholic preparations, except those mentioned in the following classes, give precipitates when mixed with **water**, the precipitate sometimes being the active principle and sometimes inert matter: tinctures, except chloride of iron, iodine, and deodorized tincture of opium; fluidextracts, except glycyrrhiza, lobelia, sanguinaria, and squills; spirits, except nitrous ether, ammonia, whiskey and brandy; wines, except white, red, and anti-monial. 14. **Water** generally causes a precipitation, when mixed with alcoholic solutions of the following substances: free alkaloids, alkaloids combined with any of the general alkaloidal reagents, glucosides, neutral and bitter principles, salicylic, gallic, or benzoic acid, volatile oils, resins, camphors, oleoresins, or balsams. 15. Among the many substances which alcohol generally dissolves may be mentioned acetates (except mercurous and silver), benzoates, bromides, chlorides (except potassium, sodium, ammonium, lead, silver, and mercurous), iodides (except lead, silver, and mercurous), nitrates (except potassium, lead, and bismuth), salicylates (except mercury and bismuth), deliquescent salts (except potassium carbonate), acids, alkali hydrates, alkali hypophosphites, phosphorus, sulphur, iodine, organic and inorganic acids (except arsenous), hydrocarbons and carbon derivatives, volatile oils, phenols, camphors, resins [see under RESINAE], oleoresins, balsams, alkaloids and their salts, glucosides, and neutral principles.

16. Inorganic substances that are insoluble in water are also generally insoluble in alcohol.

**Alkalies.**—The following preparations contain an alkali hydroxide or carbonate: ammonia water, stronger ammonia water, fluid extracts of glycyrrhiza, senega, and taraxacum, saccharated carbonate of iron, ammonia liniment, lime liniment, lime water, solution of potassium hydroxide, solution of sodium hydroxide, solution of potassium arsenite, mass of carbonate of iron, compound iron mixture, chalk mixture, mixture of rhubarb and soda, pills of carbonate of iron, spirit of ammonia, aromatic spirit of ammonia, syrup of lime, ammoniated tincture of guaiac, ammoniated tincture of valerian, syrup of rhubarb, and aromatic syrup of rhubarb. [See AQUA AMMONIA AND LIQUOR POTASSII HYDROXIDE.]

**Alkaloids.**—1. Alkaloids combine with **mineral acids** and **acetic** and **citric acids** to form salts which are generally soluble in water or alcohol, but insoluble in ether, chloroform, benzol, petroleum ether, carbon bisulphide, or oils. In combination with most other **organic acids** the alkaloids form salts that are not generally soluble in water. 2. Alkaloids combined with acids and dissolved in water or very dilute alcohol are generally precipitated as free alkaloids by solutions of **alkali hydroxides** or **carbonates** and by **borax**. Solutions of **potassium arsenite**, **sodium phosphate** and **sodium arsenate** are slightly alkaline and may precipitate the free alkaloid. M. Christiaens says: All salts whose reaction to litmus is alkaline, whatever be their chemical function, precipitate the alkaloids from their salts (D. C., XXXVIII. 59). **Ammonium carbonate** and the **bicarbonates of potassium** and **sodium** frequently do not cause precipitation. 3. The alkaloidal salts are generally precipitated from aqueous solution, combined with the precipitant, by soluble **salicylates**, **benzoates**, **bichromates**, **iodides**, **bromides**, **piperazine** and by the following general alkaloidal reagents: **tannic acid**, **picric acid**, **iodine** in solution of potassium iodide, **bromine** in solution of potassium bromide, **potassium mercuric iodide** (Mayer's reagent), **potassium bismuthic**

**iodide, mercuric chloride, lead subacetate, platinic chloride, gold chloride, and phosphomolybdic acid.** The presence of from twenty to fifty per cent. of alcohol will nearly always prevent the precipitation. 4. A solution of a mixture of **boric and salicylic acids** gives a precipitate with solutions of many alkaloidal salts as boro-salicylates. [See *ACIDUM BORICUM*, No. 19.] 5. In the presence of **acacia** some alkaloids are not precipitated from dilute aqueous solutions of their salts by tannic acid, potassium mercuric iodide, or sodium phosphomolybdate (Allen, I. 426). **Starch** dissolved by boiling in water has a similar effect with the potassium mercuric iodide. 6. Some alkaloidal salts are thrown out of solution by the presence of considerable quantities of very **soluble salts**, e.g., strychnine hydriodide by potassium iodide. 7. Some alkaloids are strong reducing agents, most alkaloids are decomposed by **oxidizing agents**. 8. The free alkaloids are generally only sparingly soluble in water, except atropine, caffeine, codeine, nicotine, and coniine, but are generally soluble in alcohol, ether, or chloroform. A few are soluble in excess of solutions of fixed alkali hydrates, e.g., morphine; a few are soluble in excess of ammonia water, e.g., quinine. 9. A strong solution of **chloral hydrate** dissolves morphine, quinine, and many other alkaloids. The solubility of the salts of the alkaloids is also increased. Dilution with water may cause a precipitation of the alkaloid.

**Aloinum.**—1. Concentrated solutions of aloin are slowly precipitated by a solution of **lead subacetate** (not the neutral lead acetate), more quickly if the mixture is heated. The liquid is turned brown. 2. An aqueous solution of aloin with **ferric chloride** gives a green-black to a brown-black color. 3. With solutions of **alkali hydroxides** aloin gives an orange to a red color, is readily decomposed, and rendered inert. 4. Concentrated **nitric acid** gives a red color with barbaloin (not with nataloin or socaloin), and by further action chrysammic, picric, and oxalic acids are formed. 5. **Gold chloride** gives a carmine red, changing to violet (U. S. D., 117). 6. **Spirit of nitrous ether** gives a red solution with aloin, even in the presence of a

large amount of water. 7. A red color is produced more or less quickly when one tenth of a grain of any of the following **alkaloids** in a dram of alcohol is added to a sixth of a grain of aloin in water, strychnine, quinine, morphine, cocaine, codeine, heroine, or hydrastine. Sometimes a violet tinge is produced which is slowly dissipated. The salts of these alkaloids, except quinine give little or no color (Bul. Pharm., XIX. 294.)

**Alumen.**—1. Alum in solution is precipitated as aluminum hydroxide by the **alkali hydroxides** and their **carbonates**, **borax**, and **lime water**. Citrates, tartrates, glycerin, sugar, and acacia tend to prevent precipitation. 2. The **alkali phosphates** give the insoluble aluminum phosphate. Citrates and tartrates tend to prevent precipitation. 3. With **tartaric acid** it gives a precipitate of potassium bitartrate. 4. **Tannic acid** or its preparations, causes a slight precipitation. 5. Alum is slightly acid to litmus. 6. Adding a **soluble carbonate** to a solution of alum produces an effervescence, due to the liberation of carbon dioxide, aluminum hydroxide being precipitated. 7. Alum has the incompatibilities of the soluble sulphates. [See ACIDUM SULPHURICUM.]

**Alumini Hydras.**—Aluminum hydrate, especially when freshly precipitated, removes suspended solid matter and coloring matter in solution from liquids.

**Alumnol, Aluminum Naphthol Sulphonate.**—1. Alumnol gives an acid solution in alcohol or water, and the solution has a blue fluorescence. 2. The aqueous solution gives a precipitate of aluminum hydroxide when an **alkali hydroxide** is added. The precipitate redissolves in an excess of the alkali. 3. The **alkali carbonates** give a white precipitate. 4. With a solution of **ferric chloride** alumnol gives a deep blue color. 5. **Silver nitrate** is not precipitated at once but is slowly decomposed and precipitated as metallic silver. 6. **Nitric acid** gives a yellow to a red color. 7. It is precipitated by a solution of **albumin** or **gelatin**, the precipitate being soluble in excess of these substances (N. S. D., 298). 8. Rubbed with **carbolic acid** it gives a mass.

**Alypin.**—1. An **alkali hydroxide** or **carbonate** gives a precipitate with an aqueous solution of alypin. 2. Mixed with **calomel** and dampened with alcohol it gives a black color.

**Ammonii Carbonas.**—1. Ammonium carbonate with **calomel** gives a black mixture of mercuric ammonium chloride, having the formula  $\text{NH}_2\text{HgCl}$ , with some metallic mercury (P. & J., 39). 2. With a solution of **mercuric chloride** it gives a white precipitate of ammoniated mercury,  $\text{NH}_2\text{HgCl}$ . 3. It gives no precipitate with **magnesium salts**, except in concentrated solutions. 4. The precipitate of **copper** or **silver** salts is dissolved by an excess of the carbonate. 5. Ammonium carbonate does not precipitate as many of the **alkaloids** from solutions of their salts, as do the carbonates of potassium and sodium. Some of the alkaloids not precipitated are atropine, hyoscyamine (except in strong solution), nicotine, coniine, codeine, and caffeine. 6. Ammonium carbonate with **resorcin** in solution gives a red-brown solution at first which changes to deep blue in a day or two. 7. Excepting the reactions noted above, ammonium carbonate acts similarly to potassium or sodium carbonate. [See CARBONATES AND AMMONIUM.]

**Ammonii Chloridum.**—1. An aqueous solution is decomposed by **chlorine**, forming hydrochloric acid and the explosive nitrogen chloride (M. & M., 1. 202). 2. Ammonium chloride aids the solution of several salts that are more or less insoluble ordinarily, and sometimes renders other salts less soluble. [See ACIDUM HYDROCHLORICUM and AMMONIUM.]

**Ammonii Iodidum.**—1. Ammonium iodide very frequently contains free iodine, and it would then have the incompatibilities of iodine. [See IODUM, ACIDUM HYDRIODICUM, and AMMONIUM.]

**Ammonii Valeras.**—Ammonium valerate in concentrated aqueous solution with **mineral acids**, gives an oily layer of valeric acid. [See AMMONIUM.]

**Ammonium.**—1. Ammonium compounds, with solutions of the **fixed alkali hydroxides** or **carbonates**, or with the **hydroxides** of barium, calcium, or strontium, give free am-

monia. 2. Some ammonium salts with **chlorine gas** give explosive nitrogen chloride. 3. Certain ammonium salts, such as the acetate, citrate, and chloride, in aqueous solution may act as solvents for otherwise insoluble compounds. [See AQUA AMMONIAE.]

**Amylis Nitris.**—1. Amyl nitrite is decomposed slowly by **light** and **air** becoming acid. 2. With **alcohol** or alcoholic preparations, it gradually forms ethyl nitrite and amyl alcohol (U. S. P., 1890, 40). 3. With **potassium hydroxide** it forms potassium nitrite and amyl alcohol (Allen, 1. 212). [See ACIDUM NITROSUM.]

**Amylum.**—1. Starch in aqueous solution is precipitated by **strong alcohol**, **tannic acid**, or **lead subacetate**. 2. **Iodine** with starch forms the blue-black iodide of starch. 3. With solutions containing over five per cent. of an **alkali hydroxide** starch forms a soluble compound. 4. **Acids** gradually change it to dextrin. **Diastase** has a similar effect. 5. In solution starch to some extent prevents the precipitation of **alkaloids** by potassium mercuric iodide and tannic acid.

**Antimonii et Potassii Tartras.**—1. Tartar emetic in aqueous solution is precipitated by **hydrochloric**, **nitric**, or **sulphuric acid**, forming a basic chloride, nitrate, or sulphate of antimony, together with some potassium bitartrate. Tartaric acid prevents this precipitation to some extent. 2. The **alkali hydroxides** or their **carbonates**, with solutions not too dilute, give a white precipitate of antimony oxide. Citrates, tartrates, glycerin, sugar, and acacia prevent precipitation. 3. **Lime water** throws down a precipitate consisting of the mixed tartrates of calcium and antimony (U. S. D., 149). 4. The salts of most **metals**, being precipitated by normal tartrates, are incompatible with tartar emetic. 5. **Strong alcohol** throws tartar emetic out of aqueous solution. 6. **Tannic acid** gives a precipitate of tannate of antimony. 7. **Gallic acid** precipitates concentrated solutions of tartar emetic. 8. In aqueous solution **mercuric chloride** is reduced to calo-

mel which is precipitated. 9. Solutions of **lead acetate**, **silver nitrate**, **albumin**, and **soap** give precipitates with tartar emetic.

**Antimonii Sulphidum.**—1. Triturated with a strong **oxidizing agent**, as potassium chlorate, sulphide of antimony may cause an explosion. 2. By exposure to **air** it is partially converted into an oxide.

**Antipyrina.**—1. Antipyrine is neutral to litmus, but forms salts with **acids** by direct addition (N. S. D., 192). 2. An aqueous solution with a strong solution of **sodium hydroxide** gives a white precipitate. 3. With a solution or tincture of **ferric chloride** antipyrine gives a red color. The red color is destroyed or prevented by an excess of mineral acids or acetic acid. 4. With commercial **ferrous sulphate** it gives a red color, due to the ferric salt which is present. With strictly ferrous salt the solution is colorless. 5. A mixture of two drams of antipyrine with one ounce of simple syrup and one ounce of **syrup of ferrous iodide** (free from iodine) soon gives a red liquid and after a time a red crystalline precipitate. 6. Antipyrine gives a green color with a solution of **copper sulphate**. 7. With a strong solution of antipyrine **lead subacetate** forms a precipitate. 8. In the presence of moisture **calomel** is slowly turned dark by antipyrine, but if sodium bicarbonate is mixed with it the color is changed at once. From Werner's experiments it would appear that metallic mercury, mercurous oxide, mercuric chloride, and antipyrine hydrochloride are formed, but the mercuric chloride will combine with the antipyrine in all probability (Ph. E., xvii. 196). 9. An aqueous solution of antipyrine is precipitated by a solution of **mercuric chloride** or by **Donovan's solution**. 10. **Alum** and **tartar emetic** are both said to be incompatible with antipyrine, but rubbing these with antipyrine or mixing aqueous solutions produces no apparent change. 11. A dilute solution of antipyrine with **nitric acid** gives a yellow color, passing into crimson on warming. 12. A solution

of **iodine** gives with a solution of antipyrine a red-brown precipitate which dissolves in an excess of antipyrine, forming a colorless solution. There is probably formed the colorless iodoantipyrine (iodopyrine) or the di-iodoantipyrine. If more iodine is added a permanent precipitate is formed which is soluble in alcohol. 13. **Bromine water** gives a precipitate which is soluble at first but remains permanent on adding more bromine. 14. The odor of **chlorine** water or a solution of chlorinated soda is destroyed by antipyrine to some extent and a precipitate may form (M. R., XII. 357). The liquid is colored yellow to red. 15. Antipyrine slowly reduces **potassium permanganate**, precipitating manganese dioxide. 16. **Chromic acid** gives an orange precipitate with a strong solution of antipyrine. 17. An aqueous solution of antipyrine gives a precipitate with **tannic acid** or preparations containing it in considerable proportions, by **picric acid** and by most of the **general alkaloidal reagents**. [See under ALKALOIDS.] 18. Antipyrine in strong aqueous solution is precipitated by a solution of a mixture of boric and salicylic acids, the precipitate dissolving at first. 19. **Spirit of nitrous ether** with antipyrine gives a green solution, and on standing green crystals are formed if the solution is concentrated. The reaction does not take place as quickly when the spirit is neutral as when it is acid, and by having a little sodium bicarbonate present the reaction may be prevented for several days or weeks. The green compound is iso-nitroso-antipyrine. The experiments of Drs. H. C. Wood and John Marshall, as well as those made by other experimenters, go to show that this compound is not a dangerous one, as Drs. Wood and Marshall gave it in doses of fifteen grains, repeated several times at intervals of an hour (D. C., XXXIII. 107). According to these investigators there is a small amount of cyanogen evolved, the quantity being so small that no danger need be apprehended. Other nitrites act similarly. 20. Crystallized **carbolic acid** when triturated with antipyrine gives an odorless liquid called phenopyrin. On mixing aqueous solutions of these two substances a turbidity results, and an oily liquid settles to the bottom in a

few hours. 21. Triturating **chloral hydrate** and antipyrine together in proper proportions forms the liquid monochloral-antipyrine, from which hypnal is made. Moderately dilute aqueous solutions of antipyrine and chloral hydrate can be mixed without separation. 22. When antipyrine and **sodium salicylate** are rubbed together a mass or liquid is formed after a time, the length of time seeming to depend on the amount of moisture in the atmosphere. It has been suggested that the simple mixture is hygroscopic, but more probably a chemical reaction takes place. Rubbing with **salicylic acid** does not give a mass or liquid. 23. Antipyrine gives a liquid or soft mass when triturated with **piperazine** and some other solids. [See page 267.] 24. Antipyrine increases the solubility of **quinine sulphate** in water, and at the same time destroys the fluorescence and prevents the green coloration which quinine gives with bromine water followed by ammonia water. 25. The solubility of **caffeine** is said to be increased by antipyrine.

**Apomorphinæ Hydrochloridum.**—1. An aqueous solution of apomorphine hydrochloride rapidly becomes green in color; the exact change which takes place has not been determined. This can be prevented by the addition of a few drops of hydrochloric or acetic acid (N. S. D., 207). It is stated that the solution will not become green if prescribed in bottles, no matter whether white or amber, that do not yield an alkali to water (Pharm. Centrabl., XLV. 843). It is slowly decomposed in boiling water. 2. An aqueous solution is precipitated by the **alkali hydroxides** and **carbonates** and by **lime water** as the free alkaloid, white at first, but quickly turning green or black. 3. Apomorphine dissolved in ammonia water develops a purple color (N. S. D., 206). 4. It is precipitated by **tannic acid**, **picric acid**, and nearly all the **alkaloidal reagents**. [See ALKALOIDS.] 5. With a concentrated solution of **ferric chloride** it gives a red precipitate, turning black. 6. Concentrated **nitric acid** added to the crystals gives a red solution. 7. Apomorphine hydrochloride in aqueous solution reduces **iodates**, **permanganates**, and **silver nitrate**.

**Aqua.**—Water precipitates from their alcoholic solutions **oils**, many free **alkaloids** or alkaloids combined with general alkaloidal reagents, some **glucosides**, some **neutral** and **bitter principles**, **resinous** or **fatty matter**, inert **extractive matter**, and nearly all compounds which are insoluble in water.

**Aqua Ammoniae.**—1. Ammonia combines with **acids** to form salts. 2. It precipitates solutions of salts of **lead**, **silver**, **mercury**, **bismuth**, **tin**, **antimony**, **copper**, **cadmium**, **iron**, **aluminum**, **chromium**, **cobalt**, **nickel**, **manganese**, and **zinc**. The precipitate is a hydroxide, except in case of silver and antimony, when it is an oxide; in case of lead, it is a basic salt; double compounds are formed in case of mercury. The precipitation many times is prevented or hindered by sugar, glycerin, acacia, citrates, tartrates, and other organic matter. 3. A solution of **corrosive sublimate** is precipitated by ammonia, giving ammoniated mercury ( $\text{NH}_2\text{HgCl}$ ). 4. **Calomel** is converted into a black mixture of metallic mercury and mercuric ammonium chloride ( $\text{NH}_2\text{HgCl}$ ) (P. & J., 39). 5. With **chlorine** ammonia forms ammonium chloride and nitrogen. If a larger proportion of chlorine gas is used, the ammonium chloride may be decomposed, forming hydrochloric acid and nitrogen. If a still larger proportion of chlorine gas is used, the ammonium chloride may be decomposed into hydrochloric acid and explosive nitrogen chloride. 6. **Bromine** acts somewhat like chlorine. 7. With **iodine** ammonium hydroxide may under certain circumstances form ammonium iodide, ammonium iodate, and water; under different circumstances, ammonium iodide and the explosive iodide of nitrogen are formed. [See IODUM, No. 2.] 8. **Permanganates** oxidize ammonium hydroxide to a nitrate. 9. With **carbolic acid** ammonia gives at first a colorless solution, which slowly becomes green, then deep blue, and finally purplish blue. 10. With **carbolic acid** and **sodium hypochlorite** ammonia produces a deep blue color. 11. With a concentrated solution of **tartaric acid** ammonia gives a precipitate of ammonium bitartrate. 12. In concentrated solutions of **picric acid** ammonia gives a precipitate. 13. **Gallic acid** gives a yellow

to a red-brown color with ammonia water. 14. **Chloral hydrate** is decomposed, giving chloroform and a formate of ammonium or chloral-ammonia. 15. Ammonia added to an alcoholic solution of **thymol** slowly gives a green color. 16. It precipitates nearly all **alkaloids** from aqueous solutions of their salts. The precipitate is the free alkaloid, and is sometimes soluble in a large excess of ammonia. 17. Spirit of ammonia has the same incompatibilities as water of ammonia, except as they are modified by the alcohol. With solutions of alkaloidal salts the ammonia liberates the alkaloids, but the alcohol has a tendency to keep them in solution. 18. Aromatic spirit of ammonia is similar to the spirit, except water causes separation of the oils.

**Aque.**—The medicating or flavoring principle in some waters is thrown out of solution by dissolving certain very soluble inorganic salts in the water; e.g., camphor water gives a precipitate of camphor when a large amount of potassium bromide is dissolved in it. To prevent this, part of the flavoring water may be replaced by distilled water.

**Aqua Hydrogenii Dioxidi.**—1. A solution of hydrogen peroxide generally contains a free mineral acid, which has been added to aid preservation. In such a case the solution would have the incompatibilities of the acid. 2. Hydrogen dioxide slowly undergoes decomposition, liberating oxygen, and if the bottle is tightly corked a sufficient pressure may be produced to burst the bottle. Heat and sunlight increase the tendency to decompose. 3. Hydrogen dioxide is a strong oxidizing agent, changing **mercurous** compounds to mercuric, **ferrous** to ferric, **arsenous** to arsenic, **hypophosphites** to phosphates, and **sulphites** to sulphates. 4. It liberates sulphur from **sulphides**. 5. With reduced **iron** and water it gives a little effervescence, and in a few hours a brown precipitate of ferric hydrate or oxide. 6. **Chromic salts** in alkaline mixtures are oxidized to a chromate. A **chromate** in the presence of an acid is reduced to a chromic salt (M. & M., II. 723). 7. Caustic **alkalies** decompose hydrogen dioxide, forming oxygen and water (M. & M., II. 724). 8. **Ammonia** in solution forms

ammonium nitrite (M. & M., II. 723). 9. **Iodides** are oxidized, liberating iodine. 10. Bromine is liberated from **hydrobromic acid**. 11. With **chlorine** hydrogen dioxide forms hydrochloric acid and oxygen (P. & J., 287). 12. Hydrogen dioxide reduces **potassium permanganate** and is itself reduced; the products in a solution acidulated with sulphuric acid are manganous sulphate, potassium sulphate, water, and oxygen. 13. It reduces **gold, silver, mercuric mercury**, and **platinum** from their oxides (P. & J., 286). 14. Hydrogen dioxide unites with some acids as **phosphoric, sulphuric, nitric**, and **hydrochloric**, forming mixtures in which it is less easily decomposed (Watts, III. 197). 15. Reaction takes place when hydrogen dioxide water and **formic aldehyde** are mixed, producing formic acid. If the mixture is made alkaline a brisk effervescence ensues. 16. It bleaches **litmus** and most organic colors. 17. Hydrogen dioxide slowly reacts with **alcohol**. 18. It gives a blue color with a tincture of **guaiaac** if the guaiaac has not been exposed to air and light too long. 19. With **tannic** or **gallic acid** it slowly gives off some gas and colors the solution yellow brown. 20. Hydrogen dioxide oxidizes **carbolic acid** to pyrocatechin, hydroquinone and quinone (M. & M., III. 832). A mixture of hydrogen dioxide water and carbolic acid becomes yellow to red brown in a few hours. 21. Hydrogen dioxide slowly changes **glycerin** to oxalic acid and carbon dioxide. 22. It coagulates a solution of **albumin** (U. S. D., 214). 23. **Phosphorus** and some substances having a strong affinity for oxygen ordinarily are unaffected by it (U. S. D., 179). 24. Some substances are not changed by it, and at the same time, have a restraining influence on its oxidizing other bodies (U. S. D., 179). 25. Quite a number of substances decompose hydrogen dioxide into water and oxygen while they themselves are not affected. Some examples of these are **manganese dioxide, sodium sulphate, potassium bromide, potassium chloride, charcoal**, and some **organic substances** (M. & M., II. 724).

**Argenti Nitras.**—I. Silver nitrate is easily changed to the oxide or metallic silver by **light** and **organic matter**. 2.

Silver nitrate in aqueous solution is precipitated as the gray-brown silver oxide by the **hydroxides** of **potassium**, **sodium**, and **ammonium**, the precipitate being soluble in ammonia water. 3. The **alkali carbonates** precipitate the yellow-white silver carbonate. 4. **Hydrochloric acid** and the soluble chlorides precipitate the white silver chloride. 5. Soluble **arsenites** precipitate the yellow silver arsenite. 6. Soluble **arsenates** precipitate the red-brown silver arsenate. 7. **Sodium phosphate** precipitates the yellow silver phosphate. 8. **Borax** precipitates silver borate, sometimes mixed with a little oxide. 9. The soluble **bromides**, **iodides**, and **cyanides** precipitate the silver bromide, iodide, and cyanide, the iodide and cyanide being soluble in excess of the precipitant. 10. **Chromates** precipitate the red-brown silver chromate. 11. **Potassium permanganate** with not too dilute solutions of silver nitrate gives a precipitate of silver permanganate. 12. It is reduced to metallic silver by metallic **zinc**, **copper**, **tin**, **mercury**, and **lead**; by **hypophosphites** and **sulphites**; in alkaline mixtures, by **arsenites**, **manganous salts**, **antimonious salts**; by **ferrous sulphate** in the cold. 13. **Tannic acid** precipitates the silver tannate. 14. Soluble **citrates** give precipitates of silver citrate. 15. Soluble **salicylates** give precipitates of silver salicylate. 16. **Morphine salts** are precipitated by silver nitrate with a red coloration. 17. Free **cocaine** gives a black precipitate, probably of silver oxide. 18. Silver nitrate in solution is reduced to the metallic condition by **glucose**, **volatile oils**, **aromatic waters**, **tartrates**, **creosote**, **formaldehyde**, and many other **organic substances**, but not generally by **alkaloids**. 19. An **alcoholic** solution of silver nitrate gradually deposits metallic silver. 20. Silver nitrate heated with **nitric acid** and **alcohol** produces the violently explosive fulminate of silver. 21. Most salts of silver, except the nitrate and chlorate, are insoluble or sparingly soluble in water.

**Argenti Oxidum.**—1. Silver oxide really parts with its oxygen, forming explosive mixtures with many substances. Triturated dry with **sulphur**, **sulphide of antimony**, **sulphide**

of **arsenic**, **phosphorus**, **tannic acid**, **creosote**, and some other **organic substances**, it is liable to explode or cause ignition. 2. Moist silver oxide decomposes many metallic salts in solution, precipitating the metallic hydroxides, e.g., salts of **bismuth**, **copper**, **iron**, and **mercury** (M. & M., IV. 470). 3. **Iodine** in water forms silver iodide and iodic acid. 4. **Chlorine** forms silver chloride and chlorate. 5. A strong solution of silver oxide in concentrated ammonia forms the explosive silver nitride ( $\text{Ag}_3\text{N}$ ) on standing or by adding alcohol (M. & M., IV. 470).

**Argonin, Silver Cascin.**—1. Argonin is slightly alkaline to litmus. 2. The aqueous solution gives a flocculent precipitate with **acids**; in case of acetic acid the precipitate dissolves in excess of acid. 3. It gives precipitates with solutions of **lead acetate**, **alum**, **silver nitrate**, **mercuric chloride**, **ferric chloride**, **copper sulphate**, **zinc sulphate**, **phenol**, and **tannic acid**.

**Argyrol, Silver Vitellin.**—1. Argyrol is precipitated from aqueous solution by **zinc sulphate**, **lead acetate**, **liquor hydrastis**, **tannic acid**, **alcohol**, and by **strong acids**: not by **alkalies**, **albumin**, or **chlorides** (N. S. D., 238). 2. A solution of **mercuric chloride** or a tincture of **ferric chloride** decolorizes a solution of argyrol at once and gives a white precipitate.

**Aristochin, Carbonic Ester of Quininé.**—1. Aristochin dissolves in **acids** and gives a bluish green fluorescence with acids containing oxygen. 2. Tincture of **iodine** added to an alcoholic solution gives a precipitate that dissolves in alcohol if too much iodine is not added. 3. It gives a deep red color with tincture of **ferric chloride**. 4. The acid solution gives precipitates with agents that precipitate quinine from its solutions. 5. It gives a mass when triturated with **menthol** or **thymol**.

**Arseni Iodidum.**—1. Iodide of arsenic in aqueous solution decomposes into arsenous and hydriodic acids. Iodine is also liberated. 2. Iodide of arsenic precipitates many **alkaloids** from solutions of their salts. 3. Its incompatibilities are similar to those of the soluble iodides and of arsenous acid. [See ACIDUM HYDRIODICUM and ARSENI TRIOXIDUM.]

**Arseni Pentoxidum.**—1. The normal alkali arsenates, as sodium arsenate, precipitate neutral solutions of salts of nearly all other common **metals**, as arsenates. Sodium arsenate is sometimes alkaline, and may cause precipitation on this account. The precipitate is soluble in mineral acids and sometimes in the presence of ammonium salts. 2. **Tannic acid** with a not too dilute solution of sodium arsenate gives a yellow-brown precipitate, the precipitate and the liquid changing to a dark green within a day or two. 3. In acid solutions arsenates are reduced to arsenites by **hypophosphites**, **sulphites**, and **iodides**, forming respectively phosphoric acid, sulphuric acid, and iodine. 4. Sodium arsenate precipitates solutions of many **alkaloidal salts**, due perhaps to the fact that the arsenate is frequently alkaline and in some cases to the formation of an insoluble alkaloidal arsenate. 5. The arsenates of the alkali metals are soluble in water. The di- and tri-metallic salts of the other metals are insoluble in water, but soluble in the presence of most mineral acids. The arsenates are generally insoluble in alcohol.

**Arseni Trioxidum.**—1. Arsenous acid combines with **alkali hydroxides** and **carbonates** to form arsenites. 2. The soluble arsenites (generally not the free acid) precipitate neutral solutions of nearly all **metallic salts**, except those of the alkalies. 3. **Ferric hydroxide** or a solution of **dialyzed iron** gives an insoluble basic arsenite with a solution of an arsenite or arsenous acid. To some extent this is changed to a basic ferrous arsenate (P. & J., 62). 4. Arsenous acid is said to combine with **potassium acid tartrate** to form a double salt, analogous to tartar emetic (Watts, v. 686). 5. A solution of **potassium iodide** with arsenous acid or potassium arsenite yields a precipitate of  $(KI)_2(As_2O_3)_3$  which is sparingly soluble in water (Watts, i. 377). One dram of potassium iodide dissolved in one dram of Fowler's solution gives only a slight precipitate. 6. Fowler's solution gives a brown-white precipitate with **lime water**. 7. With **tannic acid**, it gives a nearly white precipitate which with the liquid turns to a dark, dirty green in less than a day. 8. With

a solution of **mercuric chloride** Fowler's solution gives a white precipitate, consisting of a mercurous salt, but not if Fowler's solution is first acidified. If the Fowler's solution is in large excess there will be formed a white precipitate at first and in a few hours a dark gray precipitate of metallic mercury. 9. Fowler's solution is alkaline and may precipitate solutions of **alkaloidal salts** and other **neutral salts**. 10. Arsenous compounds are oxidized to arsenic compounds by **nitric acid**, **chlorine**, **chlorates** in acid solution, **iodine** in alkaline solution, **silver salts** in alkaline mixtures, **mercuric** or **mercurous compounds** in alkaline mixtures, **ferric compounds** in alkaline mixtures, **permanganates**, or **chromates**. 11. Arsenous compounds are reduced to metallic arsenic by **hypophosphites** in acid mixtures. 12. The solubility of arsenic trioxide is greatly increased by the presence of acids. 13. Arsenites of the alkalis are soluble in water; barium and strontium are sparingly soluble; the other metallic arsenites are insoluble. They are generally dissolved and decomposed by dilute **mineral acids**.

**Asaprol**, *Calcium Betanaphthol Sulphonate*.—1. Exposure to **air** and **light** causes asaprol to darken and become less soluble. 2. In solution it gives a precipitate with a soluble **carbonate**, **oxalate**, and other agents that precipitate calcium salts. 3. **Mineral acids** regenerate betanaphthol and precipitate it (Analyst, xxviii. 295). 4. A solution of **ferric chloride** gives a blue color. 5. **Nitric acid** gives a yellow to a red color and this with ammonia gives a yellow, due to the formation of a picrate. 6. With **mercuric nitrate** it gives a yellow color with a golden fluorescence (Analyst, xxv. 292). 7. **Formaldehyde** with sulphuric acid gives a green fluorescence. 8. Asaprol gives a precipitate with a neutral solution of **quinine sulphate**. 9. It gives a precipitate with a solution of **antipyrine**. 10. Rubbed with some solids it gives masses.

**Aspirin**, *Acetyl Salicylic Acid*.—1. Aspirin decomposes slowly when dissolved. 2. It is decomposed by **alkalies**, probably forming acetates and salicylates. 3. In solution with **potassium iodide** it slowly liberates hydriodic acid, which is oxidized

by the air, liberating iodine (M. R., xv. 140). 4. It does not give a violet color with ferric chloride solution unless it is decomposed. 5. It dissolves in aqueous solutions of alkali citrates.

**Atropina.**—1. Atropine is precipitated from concentrated aqueous solutions of its salts as the free alkaloid by **alkali hydroxides** and the **carbonates** of the **fixed alkalies** (not ammonium carbonate or the bicarbonates). 2. It is precipitated by the **general alkaloidal reagents**, except platinic chloride. [See ALKALOIDS.] 3. By continued heating with **alkali hydroxides, acids, or water**, atropine is decomposed, forming tropine and tropic acid. 4. **Chromic acid** converts it into benzoic acid (M. & M., i. 362). 5. The precipitation by **gold chloride** is prevented to some extent by the presence of a little sodium thiosulphate.

**Auri et Sodii Chloridum.**—1. Gold and sodium chloride precipitates many of the **alkaloids** from solutions of their salts as double compounds. The addition of sodium thiosulphate to the chloride before mixing with the alkaloidal solution tends to prevent precipitation. If one fourth of a grain of sodium thiosulphate be dissolved in one dram of water and added to one eighth of a grain of gold and sodium chloride dissolved in one dram of water, and this added to one eighth of a grain of strychnine sulphate in two drams of water, no precipitation will take place at once or for several days. Using one half as much water as above stated, a precipitate may be slowly formed. If one fourth the amount of water is used precipitation will usually take place within a day. 2. **Potassium iodide** added to a solution of gold chloride (the latter being in excess) precipitates the yellow aurous iodide and liberates iodine. But if the solution of gold chloride is added to the potassium iodide solution (the latter being in excess), there is first formed a dark green solution of potassium auric iodide, then a precipitate of auric iodide which is instable, decomposing in pure water forming aurous iodide (P. & J., 92). 3. Gold chloride combines with and precipitates **albumin**. 4. Gold chloride in solution is reduced to metallic gold by metallic **silver, mercury, copper,**

and iron; 5. by mercurous salts, arsenites, ferrous sulphate, and many organic substances; 6. by hypophosphorous, sulphurous, nitrous, oxalic, and tannic acids; 7. by light and heat.

**Barium.**—Barium salts in aqueous solution are precipitated by **sulphuric acid** and soluble **sulphates**, by aqueous solutions of **phosphates**, **tartrates**, **oxalates**, **carbonates**, **chromates**, or **tannic acid**, the precipitate being barium sulphate, phosphate, tartrate, oxalate, carbonate, chromate, or tannate.

**Betanaphthol.**—1. Betanaphthol in aqueous solution imparts a pale green color when **ferric chloride** is added, and slowly deposits dinaphthol (M. & M., III. 460). 2. Warming with **sulphuric acid**, naphthol forms a sulphonc acid (Allen, II. pt. II. 203). 3. **Chlorine** or **chlorinated lime** colors a solution of naphthol a pale green or yellow (Allen, II. pt. II. 203). 4. A cold saturated aqueous solution of naphthol gives a faint bluish fluorescence with **ammonia** (U. S. D., 236). 5. **Alkaline potassium permanganate** oxidizes it to ortho-carboxy-cinnamic acid (M. & M., III. 460). 6. Betanaphthol when triturated with some solids gives a liquid or a soft mass.

**Betol, Betanaphthol Salicylate.**—1. Betol in alcoholic solution with **ferric chloride** gives a red to red-violet color. 2. Triturated with **chloral hydrate** it slowly gives a mass. 3. It is decomposed by **alkalies** into betanaphthol and a salicylate.

**Bismuthi et Ammonii Citras.**—1. Citrate of bismuth and ammonium in aqueous solution is precipitated as the bismuth citrate by most mineral **acids** and the stronger organic acids. 2. It is not readily precipitated by the **fixed alkali hydroxides**, but these on heating liberate ammonia.

**Bismuthi Subgallas, Dermatol.**—1. Bismuth subgallate is decomposed by strong **acids** with liberation of gallic acid. 2. **Alkali hydroxides** dissolve it, giving a yellow solution which becomes red.

**Bismuthi Subnitrates.**—1. Bismuth subnitrate is slowly

decomposed by **water**, liberating nitric acid and forming a more basic nitrate. 2. It is converted into the hydroxide by solutions of the **alkali hydroxides**. 3. In the presence of water the **alkali carbonates** and **bicarbonates** convert it into the subcarbonate, and at the same time some carbon dioxide is liberated. 4. Soluble **iodides** change bismuth subnitrate to an iodide. [See No. 10, under ACIDUM HYDRIODICUM.] 5. **Hypophosphites** reduce bismuth subnitrate to metallic bismuth (P. & J., 296). 6. **Chlorine**, **chlorinated lime**, and **hydrogen dioxide**, in alkaline mixtures convert the bismuth into the reddish peroxide (P. & J., 104). 7. **Tannic acid** in the presence of water slowly forms the yellow tannate of bismuth. 8. With a solution of **sodium salicylate** bismuth subnitrate is said to form a series of nitro-salicylates, varying in color from white to red orange. Mixtures of these in various proportions made in the author's laboratory showed no perceptible change even on standing. 9. **Tragacanth** with water and bismuth subnitrate gives curdy masses which stick to the sides of the bottle. 10. Bismuth subnitrate is soluble in **glycerin**, but should not be triturated with it for fear of an explosion (Scoville, 287).

**Bismuthi Subsalicylas.**—1. Bismuth subsalicylate with a solution of a **ferric salt** gives a violet color. 2. It is decomposed by **acids** and **alkalies**.

**Bromalum Hydratum.**—1. Bromal hydrate is decomposed by **alkali hydroxides**, forming bromoform and a formate (N. S. D., 410). 2. With **alcohol** it forms bromal alcoholate (M. & M., 1. 540). 3. It forms a liquid or mass when triturated with **hedonal**, **trional**, and some other solids. [See page 267.]

**Bromoformum.**—1. Bromoform turns yellow in the light. 2. **Potassium hydroxide** converts it into a bromide and a formate of potassium. 3. With alcoholic **potash** bromoform is decomposed, producing potassium bromide, carbon monoxide, ethylene, and water (Allen, 1. 241).

**Bromum.**—1. Bromine with **alkali hydroxides** forms bromides and bromates. 2. With **sulphites** it forms sulphates

and bromides. 3. With **hypophosphites** it forms phosphates and bromides. 4. **Metallic mercury** and **mercurous compounds** are oxidized to mercuric compounds. 5. **Arsenites** are converted into arsenates. 6. **Ferrous salts** are converted into ferric salts, and in alkaline mixtures into ferrates. 7. Bromine bleaches vegetable **colors**. 8. It combines with many **fixed oils** containing olein, forming addition products. 9. With oil of **turpentine** and some other **volatile oils** it is liable to react violently and may cause ignition. 10. Bromine in **water** gradually forms hydrobromic acid and oxygen (M. & M., I. 536). 11. An **alcoholic solution** is gradually decolorized, forming hydrobromic acid. 12. With **hydrogen dioxide** oxygen is evolved.

**Butyl Chloral Hydras.**—1. Butyl chloral hydrate (erroneously called croton chloral hydrate) gradually undergoes decomposition in aqueous solution. 2. With **alkalies** it is decomposed, producing a formate and propylic chloroform, which splits up with the formation of a chloride of the alkali and dichloride of allylene (Allen, I. 231). 3. It liquefies or gives a soft mass when triturated dry with several solids. [See page .]

**Cadmium.**—The soluble cadmium salts in aqueous solution are precipitated by the **alkali hydroxides** forming white cadmium hydroxide; by **alkali carbonates**, forming the white cadmium carbonate; by the soluble **sulphides** and **hydrosulphuric acid**, as the yellow cadmium sulphide; by the **alkali chromates**, as the yellow cadmium chromate; by the soluble **phosphates**, as the white cadmium phosphate.

**Caffeina.**—1. Caffeine does not readily combine with **dilute acids**, although it unites with concentrated acids. The salts are easily decomposed by water, alcohol, or ether. 2. Caffeine in moderately dilute solutions is not precipitated by the **alkali hydroxides** or **carbonates** or the **general alkaloidal reagents**, but from strong solutions it is precipitated by **tannic acid**, **phosphomolybdic acid**, **silver nitrate**, and **mercuric chloride**. 3. Warmed with alcoholic **potassium hydroxide** it forms methylvamine, carbon dioxide, and a little

ammonia (N. D., 331). 4. A solution of citrated caffeine contains free citric acid which may give trouble sometimes. 5. The solubility of caffeine is increased by the presence of sodium salicylate, sodium benzoate, antipyrine, and potassium bromide (N. S. D., 330).

**Calcium.**—1. The soluble calcium salts in concentrated solutions are precipitated by the **fixed alkali hydroxides** as calcium hydroxide; 2. by soluble **sulphates** in not too dilute solutions as sulphate; 3. by soluble **carbonates, phosphates, oxalates, or tartrates** as calcium carbonate, phosphate, oxalate, or tartrate. 4. Soluble **citrate**s on heating precipitate the calcium citrate.

**Calcii Hypophosphis.**—1. Calcium hypophosphite in aqueous solution gradually changes to calcium phosphate. 2. Excess of sugar throws calcium hypophosphite out of solution (Scoville, 287). 3. The presence of hypophosphorous acid increases its solubility in water. [See CALCIUM and ACIDUM HYPOPHOSPHOROSUM.]

**Calcii Phosphas.**—Calcium phosphate forms soluble compounds with nearly all **acids** except those which precipitate calcium salts.

**Calx.**—1. Lime exposed to **air** absorbs carbon dioxide and water. 2. Its solubility is greatly increased by **glycerin** or **sugar**, probably by forming loose combinations. 3. Lime decomposes most **salts**, combining with their acids. 4. It combines with **water** to form calcium hydroxide which has many of the incompatibilities of the fixed alkalies. [See CALCIUM and LIQUOR POTASSII HYDROXIDI.]

**Calx Chlorata.**—1. Chlorinated lime contains calcium hypochlorite, which on account of the easily liberated chlorine makes it a strong oxidizing agent. Other hypochlorites act similarly. 2. It is decomposed by **heat, light, acids, and carbon dioxide**, liberating chlorine. 3. It converts **sugar, starch, cellulose**, and similar substances into formic acid (U. S. D., 268). 4. With **alcohol**, some **volatile oils**, or **wood alcohol**, it generates chloroform (N. S. D., 349). 5. Mixed with

**glycerin** it reacts violently, giving off white fumes and turning the mass brown. The ultimate products of the oxidation are oxalic acid and carbon dioxide. 6. With **organic substances** in a dry state chlorinated lime causes gradual decomposition with the development of heat, and may cause explosion. [See CHLORUM, CALCIUM, and ACIDUM HYDROCHLORICUM.]

**Calx Sulphurata.**—Sulphurated lime is decomposed by **mineral acids** and **carbon dioxide**, liberating hydrogen sulphide.

**Cambogia.**—1. Gamboge gives an orange-red solution with a solution of **sodium** or **potassium hydrate** and the color caused by the latter reagent changes to yellow brown. 2. With **ammonia water** it gives a yellow solution, changing to red and finally brown. 3. With a tincture of **iron** it gives a black-brown solution. 4. The resin forms salts with some heavy metals (N. S. D., 353).

**Camphora.**—1. Camphor when oxidized by **nitric acid** forms camphoric acid which is insoluble in water, and camphoronic acid which is soluble (M. & M., I. 669). 2. With **chromic acid** it forms camphoronic acid (M. & M., I. 669). 3. **Potassium permanganate** in alkaline solution converts camphor into camphoric acid (M. & M., I. 669). 4. **Bromine** unites with it to form the crystallizable instable dibromide of camphor, which on heating breaks up into hydrobromic acid and monobromated camphor (Allen, II. 447). 5. **Iodine** acts on camphor, when heated, with evolution of hydriodic acid, and formation of cymene, carvacrol, laurine, and other bodies the nature of which has not been determined (R. & S., III. part v. 427). Iodine dissolved with a large excess of camphor in alcohol still gives the iodine reaction with starch after several days. 6. **Chlorine** has no action on camphor but in the presence of alcohol it forms chlorinated compounds (M. & M., I. 669). 7. Camphor absorbs the gases of **hydrochloric acid**, **sulphur dioxide**, and **nitric peroxide**, forming colorless liquids, which are decomposed on adding

water (Allen, II. 446). 8. Solutions of camphor in alcohol and ether increase the solubility of **corrosive sublimate** and the presence of this salt increases the solubility of camphor in these liquids (N. S. D., 355). 9. **Sugar, magnesia, milk or carbonic acid** make it more soluble in water (A. D., 416). 10. When camphor is triturated with dragon's blood, galbanum, guaiacum, or asafoetida, the mixture preserves its pilular consistency indefinitely. With benzoin, tolu, mastic, and ammoniac, the mixture becomes soft on exposure to air. With olibanum, gamboge, and myrrh, the mixture remains pulverent, though grumous. Asafoetida, galbanum, tolu, dragon's blood, olibanum, mastic, benzoin, guaiac, and ammoniac destroy to a greater or less extent the odor of camphor. Heated with resins or fats, camphor unites in all proportions (A. D., 416). 11. Camphor is thrown out of its aqueous solution by dissolving large amounts of **metallic salts** in the water. 12. Camphor produces a liquid or soft mass when triturated with about an equal weight of **betol, guaiacol carbonate**, and many other solids. [See page 267.]

**Camphora Monobromata.**—1. Monobromated camphor with **nitric acid** forms bromo-nitro-camphor and camphoric acid (N. S. D., 357). 2. With alcoholic **potash** it forms camphor (M. & M., I. 670). 3. When triturated with **carbolic acid, chloral alcoholate, chloral hydrate, euphorin, pyrocatechin, salol, or thymol** it gives a liquid or soft mass.

**Cannabis Indica.**—1. **Water** added to an alcoholic extract of cannabis indica causes the precipitation of a large amount of resinous matter. This resinous matter is soluble in a concentrated aqueous solution of chloral hydrate.

**Cantharidin.**—1. Cantharidin combines with **alkalies**, forming soluble cantharidates. 2. It is precipitated from solutions by **neutral lead acetate, silver nitrate, mercuric chloride, and copper sulphate**.

**Carbo.**—1. Charcoal absorbs many gases, such as **ammonia, hydrogen sulphide**, etc. 2. When mixed with solutions it absorbs and removes from solution **tannic acid**, many **alkaloids**, many **glucosides**, and a number of **bitter** and

odorous principles, coloring matter, fusel oil, iodine, and many metallic salts (N. S. D., 367). 3. When triturated with oxidizing agents, such as potassium chlorate or potassium permanganate, there is danger of an explosion.

**Carbonates.**—1. Carbonates are decomposed by all common acids except hydrosulphuric and hydrocyanic acids, and by some metallic acid salts, with liberation of carbon dioxide. 2. Solutions of potassium and sodium carbonates precipitate solutions of salts of all other common metals; the precipitate is a normal carbonate in case of silver, mercurous mercury, cadmium, ferrous iron, manganese, barium, strontium, and calcium; it is a hydroxide in case of tin, aluminum, ferric iron, and chromium; it is an oxide in case of antimony; it is a basic carbonate in case of lead, nickel, bismuth, copper, zinc, cobalt, magnesium, and mercuric mercury. Mercuric chloride is precipitated as the basic chloride. 3. The carbonates of the alkalies precipitate as free alkaloids the aqueous solutions of most alkaloidal salts and decompose a few of the alkaloids. 4. In the presence of water bismuth subnitrate liberates carbon dioxide from the alkali carbonates. 5. Ammonium carbonate causes reactions similar to potassium carbonate, except with resorcin and salts of mercury, copper, silver, and alkaloids. [See AMMONII CARBONAS.] 6. The carbonates of the alkalies are soluble in water. The other normal or basic carbonates are insoluble in water, although many are soluble in excess of carbon dioxide, forming bicarbonates. The carbonates are insoluble in alcohol.

7. The bicarbonates of the alkalies have about the same incompatibilities as the carbonates, although they do not precipitate as many of the alkaloidal or metallic salts. 8. The pure bicarbonates do not precipitate solutions of salts of atropine, hyoscyamine, nicotine, quinine, quinidine, cocaine, coniine, codeine, brucine, or caffeine, unless the solution be quite concentrated or heat be applied (Sohn). 9. Sodium bicarbonate with a solution of mercuric chloride produces an effervescence and gives a white precipitate at first which changes

to a brown or purple on standing, the change taking place more quickly when the mercury is in excess. Various oxychlorides of mercury are formed (M. & M., III, 217). 10. **Heating** the alkali bicarbonates dry or in aqueous solution changes them to some extent to the normal carbonates.

**Catechu.**—1. Catechu contains a large percentage of tannic acid. [See ACIDUM TANNICUM.] 2. Catechu-tannic acid does not precipitate solutions of tartar emetic, but an aqueous solution of the acid is precipitated by **gelatin** and **albumin**, 3. Catechu-tannic acid gives a greenish-black solution or precipitate with a solution of **ferric salts**.

**Cerii Oxalas.**—1. Cerium oxalate with **alkali hydroxides** slowly forms the cerium hydroxide and the oxalate of the alkali. 2. It dissolves in dilute **hydrochloric acid** or dilute **sulphuric acid**, and this solution is precipitated by the alkali hydroxides or carbonates.

**Chloralformamidum.**—1. Chloralamide is decomposed by warm **water** or by **alkalies**, giving chloral hydrate and formamide (N. S. D., 405). The chloral is further decomposed by the alkali giving chloroform and a formate. 2. It reduces **silver nitrate**. 3. Rubbed with **antipyrine** or **menthol** it gives a mass.

**Chloralum Hydratum.**—1. Chloral hydrate in aqueous solution slowly undergoes decomposition, forming traces of hydrochloric acid. A neutral alcoholic solution remains permanently neutral (N. S. D., 407). 2. An aqueous solution, with **alkaline hydroxides**, **alkaline carbonates**, or **borax**, produces chloroform and a formate of the base. 3. **Potassium permanganate** oxidizes it, forming chloroform, chlorine, carbon dioxide, and oxygen (M. & M., II, 4). 4. Chloral hydrate unites with **hydrocyanic acid** to form chloral-hydrocyanate (Richter, 196). In concentrated solution potassium permanganate oxidizes it to trichloroacetic acid (N. S. D., 407). 5. With **potassium cyanide** it forms dichloroacetic acid (M. & M., II, 4). If chloral hydrate and potassium cyanide are rubbed together dry in a mortar, chemical reaction takes place with almost explosive

violence, and a large amount of white fumes are given off, leaving a brown mass. If the two are powdered separately, and mixed lightly, the reaction is slower, but a brown mass finally results. 6. In aqueous solution with **potassium iodide** chloral hydrate slowly gives chloroform and iodine (M. & M., II. 2). 7. With **alcohol** in the presence of **water** and certain soluble salts, as potassium or sodium bromide, chloral hydrate forms chloral alcoholate, which may separate as an oily liquid. Further addition of alcohol may cause the liquids to mix. This formation does not take place in the presence of ammonium or calcium bromides, ammonium chloride, or potassium nitrate (Scoville, 296). 8. Chloral hydrate in concentrated aqueous solution is a good solvent for **resinous matter**. It also dissolves **morphine**, **quinine**, and other **alkaloids** to some extent, some glucosides, neutral principles, volatile oils, fats, and coloring principles. 9. A concentrated aqueous solution of chloral hydrate is said to be a good solvent for **starch**, and on adding iodine a cherry-red color is produced instead of the blue. Experiments made by the writer always gave the blue color. 10. Chloral hydrate increases the solubility of acetanilide in water. 11. **Camphor** forms an unstable liquid compound when rubbed with chloral hydrate. 12. Chloral hydrate gives a product varying from a stiff mass to a liquid when triturated dry with about an equal weight of agurin, antiseptin, guaiacol carbonate, salocoll, hedonal, quinine sulphate, trional, and many other solids. [See page 267.] 13. It softens oil of theobroma when rubbed with it.

**Chloral Alcoholate.**—1. Chloral alcoholate is decomposed by **sulphuric acid**, liberating chloral (M. & M., II. 4). 2. It liquefies or gives a soft mass when triturated with many solids. [See page 267.]

**Chlorates.**—1. Chlorates are liable to cause an explosion when triturated dry or heated with **sulphur**, **sulphides**, **sulphites**, **cyanides**, **thiosulphates**, **hypophosphites**, **nitrites**, **reduced iron**, **amorphous phosphorus**, **iodine**, **ammonium picrate**, **tannic acid**, or substances containing it, **gallic acid**, **carbolic acid**, **oxalic acid**, **charcoal**, **sugar**, **honey**, **glycerin**,

**starch, lycopodium, salicylic acid, shellac**, and many other oxidizable substances. 2. Chlorates with **sulphuric acid** detonate or explode, forming chlorine peroxide and a perchlorate. 3. With **hydrochloric acid** chlorates give chlorine and oxides of chlorine. [See CHLORUM.] 4. In neutral or alkaline solutions chlorates do not usually have an oxidizing effect. 5. Potassium chlorate with potassium iodide is said to form potassium iodate and potassium chloride (Nat. Drug, xxvii, 232). 6. The metallic chlorates are soluble in water and are generally soluble in alcohol, except potassium.

**Chloretone.**—1. Chloretone gives a mass or liquid when triturated with an equal weight of **antipyrine, euphorin, exalgine, menthol, or phenol**.

**Chloroformum.**—1. Chloroform when pure is decomposed by **air and light** into chlorine, carbonyl, chloride ( $\text{COCl}_2$ ), and other products; this is prevented by having some oxidizable substance present, as sulphur or alcohol (N. S. D., 412). The vapors coming in contact with gas light produce chlorine vapors (Merck's Index, 1907, p. 137). 2. The solubility in water is increased by **citric acid** (Bul. Pharm., xiii. 165).

**Chlorum.**—1. Chlorine with a solution of a **hydroxide** of a **fixed alkali** or an **alkaline earth** forms a chloride and a chlorate. If the chlorine is added short of saturation a hypochlorite is formed. 2. With **ammonia water** chlorine gives ammonium chloride and a little nitrogen, or if the ammonia is in excess a little chlorate. If chlorine is in excess explosive nitrogen chloride may be formed. 3. With some **salts** of **ammonium** chlorine is liable to form the explosive nitrogen chloride. 4. Chlorine precipitates solutions of salts of **lead, mercurous mercury, and silver** as chlorides. 5. Chlorine water after standing a while is changed to hydrochloric acid. 6. Chlorine is a strong oxidizing agent, and is itself reduced to a chloride by the agents which it oxidizes. With **iodides** it forms iodine and then iodic acid, and in the presence of an alkali a periodate. 7. With **bromides** it forms bromine and in alkaline mixtures a bromate. 8. With **hypophosphites** phosphates are formed.

9. **Sulphites** or **sulphides** are changed to **sulphates**. 10. **Mercurous, arsenous** or **ferrous compounds** are changed to mercuric, arsenic, or ferric compounds in acid or alkaline mixtures. 11. With **hydrogen dioxide** oxygen is liberated. 12. **Salicylic acid** is changed to mono- and di-chloro-salicylic acid (M. & M., III. 680). 13. **Glycerin** is converted into oxalic acid and carbon dioxide. 14. Chlorine is rapidly absorbed by **alcohol**. [See ALCOHOL, No. 5.] 15. Chlorine bleaches **indigo, litmus**, and other organic colors. 16. It oxidizes nearly all **organic matter**.

**Chromii Trioxidum, Chromic Acid.**—1. Chromic acid combines with the **alkali hydroxides** to form yellow normal chromates and red dichromates. 2. Chromic acid, or chromates in solution with sulphuric acid, are reduced to chromic salts by **tartrates**, producing formic acid, carbon dioxide, and water; 3. by **oxalates**, forming carbon dioxide; 4. by **hypo-phosphites** (no action in alkaline mixtures), forming phosphoric acid; 5. by **sulphides**, liberating sulphur; 6. by **sulphites**, forming sulphuric acid; 7. by **chlorides**, liberating chlorine; 8. by **bromides**, liberating bromine; 9. by **iodides**, liberating iodine; 10. by **dilute alcohol**, forming aldehyde, and acetic acid. 11. Chromic acid, with **strong alcohol, glycerin, ether, volatile oils**, or other readily oxidizable matter, is liable to cause an explosion or fire. 12. The soluble chromates and bichromates precipitate aqueous solutions of salts of **lead, silver, mercury, bismuth, manganese, barium, and strontium** as chromates, generally normal, varying in color from yellow to red. 13. Potassium bichromate precipitates many alkaloids from aqueous solutions of their salts, e.g., **atropine, codeine, hydrastine, quinine, strychnine, morphine** (only in concentrated solutions, 1 : 100). The normal potassium chromate does not precipitate as many of the alkaloids as the bichromate. 14. Bichromates are liable to cause an explosion when triturated with **tannic acid, sugar**, or other substances that are easily oxidized. 15. The chromates of the **alkalies, magnesium, calcium, and zinc** are soluble in water; the others are sparingly soluble. They are nearly insoluble in alcohol.

**Chrysarobinum.**—1. Yields chrysophanic acid on oxidation. 2. Dissolves in aqueous solutions of the **alkalies** giving a red liquid with a greenish fluorescence. 3. **Lime water** gives a violet color.

**Cinchona.**—1. Cinchona contains a sufficient amount of tannic acid to make its preparations incompatible with many metallic **salts** and other compounds. [See ACIDUM TANNICUM.] 2. The tannic acid gives a color varying from brown to blackish green with solutions of **ferric salts**. 3. The cinchona alkaloids in solution form compounds with the **general alkaloidal reagents**, which compounds are nearly insoluble in water but soluble in alcohol. [See ALKALOIDS and QUININA.]

**Citrophen, Paraphenetidin Citrate.**—1 It gives a dark red color with a solution of **ferric chloride**.

**Cocaina.**—1. Cocaine is precipitated from aqueous solutions of its salts by the reagents that usually precipitate alkaloids. [See ALKALOIDS, Nos. 2 and 3.] 2. Cocaine is quite easily decomposed by strong **acids**, strong solutions of **alkali hydroxides**, or by **hot water**, forming methyl alcohol, benzoic acid, and ecgonine. 3. Mixed with **calomel** in the presence of moisture cocaine hydrochloride turns the mixture gray or even black, due probably to the reduction of some of the calomel to metallic mercury, while at the same time some mercuric chloride is formed. The mercuric chloride then combines with the alkaloid to form a compound insoluble in water. The free alkaloid cocaine mixed with calomel does not readily darken, but may be made to do so by blowing the fumes of hydrochloric acid over it. 4. A concentrated solution of cocaine hydrochloride is precipitated by a solution of **chromic acid** or potassium permanganate.

**Codeina.**—1. Codeine in aqueous solution is not precipitated by alkaline carbonates, bicarbonates, or ammonium carbonate, but is precipitated by most of the other **alkaloidal reagents**. [See ALKALOIDS, Nos. 2 and 3.] 2. Codeine in aqueous solution gives a precipitate with solutions of salts of **iron, lead, copper**, and some other **metals** (N. D., 455). This

is probably due to the fact that it is quite strongly alkaline and one of the most soluble of the alkaloids. 3. With some **ammonium salts**, as ammonium chloride, codeine liberates ammonia. 4. If codeine is added to a solution of a **morphine salt** morphine is set free and usually precipitated. 5. **Nitric acid** gives a yellow solution with codeine.

**Colchicina.**—1. Colchicine is darkened by exposure to light. 2. It is precipitated from aqueous solution by most of the **general alkaloidal reagents**, unless the solution is quite weak. 3. Colchicine is readily decomposed by strong **acids** or strong solutions of **alkalies**, forming colchicine. Acids generally give a yellow color. Nitric acid gives a blue to a violet color turning brown and then yellow (Sohn, 42). Potassium hydroxide gives a red color (N. S. D., 460). 4. Most of its salts are decomposed by **water** (M. & M., II. 234.)

**Collodium.**—1. Collodion is gelatinized by **carbolic acid** and by a large excess of **creosote**. Alcohol renders the mass more fluid. 2. **Water** separates the gun-cotton. [See PYROXYLINUM.]

**Coniina.**—1. Coniine becomes yellow and resinoid on keeping and gives off ammonia (U. S. D., 394). 2. It is not precipitated by the alkali hydroxides or carbonates, but it is by the **general alkaloidal reagents**, except platinic chloride. [See ALKALOIDS.] 3. Coniine coagulates **albumin**. 4. It precipitates solutions of salts of **aluminum**, **copper**, **zinc**, **manganese**, **iron**, and **silver**; the precipitate with silver is soluble in excess of the alkaloid (U. S. D., 394). 5. It forms butyric acid when treated with most **oxidizing agents**. 6. An alcoholic solution of **iodine** with coniine gives a brown precipitate, which afterwards disappears, and the liquid becomes colorless (M. & M., II. 246). 7. Vapors of coniine coming in contact with those of **hydrochloric acid** give white fumes.

**Copaiba.**—1. Copaiba, with the **hydroxides of the alkalies** or **alkaline earths**, forms saponaceous compounds, in which the resin acts the part of an acid. 2. With one sixteenth of its weight of **magnesia** which has been dampened with water,

the resin of the copaiba combines slowly to form a solid mass. A similar change is produced by **calcium hydroxide** (U. S. D., 398).

**Creosoti Carbonas, Creosotal.**—1. Creosote carbonate is decomposed by **alkalies**, liberating creosote.

**Creosotum.**—1. Creosote reduces some of the **inorganic salts**, such as salts of silver, gold, and copper, to the metallic state. 2. If mixed suddenly or triturated dry with strong **oxidizing agents** it is liable to cause an explosion. 3. It precipitates solutions of **albumin** and **gum** (not gelatin) (N. S. D., 497). Creosote in large excess gelatinizes **collodion**. 4. Creosote with solutions of **ferric salts** gives a violet-blue color, changing to greenish brown, and, unless in very dilute solution, a brown precipitate is formed. An alcoholic solution of creosote with an alcoholic solution of ferric chloride gives a bluish-green color (U. S. D., 404). 5. Triturated with **silver oxide**, an explosion is liable to take place. 6. With concentrated **nitric acid** reddish fumes of the oxides of nitrogen are given off. With dilute nitric acid a brown resin is formed (U. S. D., 404). 7. With concentrated **sulphuric acid** it gives a red color, becoming black on adding more acid. 8. Creosote gives a white precipitate with solution of **lead subacetate**. 9. Creosote dissolves a large number of metallic salts and reduces some of them to the metallic condition (U. S. D., 403).

**Cresol.**—1. Cresol dissolves in solutions of **alkali hydroxides**. 2. A dilute solution with a solution of **ferric chloride** gives a blue violet (N. S. D., 499).

**Cupri Sulphas.**—1. Copper sulphate is precipitated by the **fixed alkali hydrates** as blue copper hydrate, which on standing becomes basic and black. This precipitation is more or less prevented by citrates, tartrates, salicylates, sugar, milk sugar, glycerin and other organic substances. A solution of copper sulphate and acacia is gelatinized by the alkali hydrates. 2. **Ammonia water** precipitates the cupric hydrate and in excess dissolves it, forming an intense blue solution. This solution dissolves cotton, filter paper, and other forms of cellu-

lose. 3. **Ammonium carbonate**, like ammonia water, precipitates the copper and then redissolves it, forming a blue solution. 4. The **carbonates** of the **fixed alkalies** precipitate the copper as a basic carbonate of variable composition. 5. In neutral solutions the soluble **phosphates** give a blue-white precipitate of copper phosphate. 6. **Arsenites** in neutral solution give a green precipitate of copper arsenite. 7. Soluble **iodides** reduce and precipitate copper sulphate as cuprous iodide ( $\text{Cu}_2\text{I}_2$ ), iodine being liberated. 8. In alkaline mixtures cupric compounds are reduced to cuprous oxide by **arsenous acid**, **glucose**, and many organic substances. 9. Copper sulphate coagulates a solution of **albumin**. 10. **Tannic acid** precipitates a solution of copper sulphate, and with heat reduces the copper. 11. **Sodium salicylate** with copper sulphate in solution gives a green color, and the copper is not precipitated from dilute solution by alkalies. 12. **Antipyrine** gives a green color to a solution of copper sulphate.

**Decocta.**—The incompatibilities of decoctions are similar to those of infusions. [See *INFUSA*.]

**Digitalis.**—1. Digitalin is precipitated from solutions by **tannic acid** and **chloride of gold**, not by most of the other alkaloidal reagents (Sohn, 49). 2. With **nitric acid** digitalin gives at first a colorless solution, changing to yellow or green (Sohn, 50). 3. Digitonin is precipitated from aqueous solution by **ammonia**, **tannic acid**, or **lead acetate** (Sohn, 50). 4. All of the principles of digitalis are quite easily decomposed by strong **acids** or **alkalies**.

**Diuretin.**—1. Sodio-theobromine salicylate in aqueous solution is strongly alkaline, and is decomposed by **acids**, even the carbon dioxide in the air, with precipitation of probably both theobromine and salicylic acid. 2. **Alkali carbonates** (not hydroxides), **sodium phosphate** and **borax** slowly give precipitates. 3. Diuretin in excess gives precipitates with solutions of many **metallic salts**. 4. With a solution of **ferric chloride** it gives no precipitate but a violet to red color on account of the salicylate. 5. It reduces salts of silver and mercury (Scoville,

297). Calomel is darkened at once by diuretin. 6. Tincture of **iodine** is decolorized at first but added in excess it gives a precipitate. 7. It precipitates some **alkaloids** from solution of their salts. 8. Rubbed with **piperazine** and some solids it gives a mass or liquid. [See page 267.] 9. It has the incompatibilities of a salicylate, theobromine, and an alkali.

**Elaterinum.**—1. Elaterin combines with the **alkali hydroxides** to form compounds soluble in water, from which solution acids precipitate the elaterin. 2. It is precipitated from alcoholic solution by **lead acetate** and **silver nitrate** (Watts, II. 373).

**Emulsa.**—Emulsions are broken up by substances which precipitate the emulsifying agent. [For emulsions made with acacia, see ACACIA].

**Ergota.**—The active principles of ergot are generally precipitated by **tannic acid**, **metallic salts**, **potassium mercuric iodide**, and some of the **general alkaloidal reagents**.

**Erythrol Tetranitrate.**—1. Erythrol tetranitrate is decomposed by **warmth** and **sunlight** turning yellow and giving off nitrous fumes (U. S. D., 1480). 2. Triturated with **glucose** it has caused explosion.

**Eucaina.**—1. Eucaine hydrochloride A in solution is precipitated by **alkali hydroxides**, **carbonates**, **potassium permanganate**, **mercuric chloride** and **potassium iodide**, and it is colored red by **ferric chloride** (N. S. D., 578). 2. Eucaine hydrochloride B in solution is precipitated by alkalies and their carbonates, but not by mercuric chloride from a five per cent. solution (N. S. D., 578).

**Eucalyptol.**—Eucalyptol is oxidized to cineolic acid by **potassium permanganate** (M. & M., II. 526). 2. **Iodine** in potassium iodide gives green crystals; **bromine** gives red crystals; **naphthol** gives addition products (N. S. D., 580).

**Euphorin, Phenyl urethane.**—1. Euphorin gives a mass or liquid when triturated with **hedonal**, **trional** and many other solids. [See page 267.]

**Euophen, Isobutyl-orthocresol Iodide.**—1. Euophen is

soluble in alcohol, ether, and fixed oils. 2. **Heat** and **light** tend to liberate iodine, particularly in solution. 3. The solution in **oil** is of doubtful efficiency, since the iodine slowly liberated combines with the oil. 4. It is not advisable to prescribe it with substances that have a strong affinity for iodine, as oxides, hydroxides, starch, salts of mercury. 5. An alcoholic solution gives a yellow, flocculent precipitate with **mercuric chloride**.

**Exalgina, Methyl Acetanilide.**—1. Exalgine liquefies or gives a mass when triturated with many solids. [See page 267.]

**Ferripyrine.**—1. **Light** decomposes ferripyrine. 2. **Alkali hydroxides, carbonates, and bicarbonates** precipitate ferric hydroxide from aqueous solutions (N. S. D., 195).

**Ferri Phosphas Solubilis.**—1. The soluble phosphate of iron, being made by mixing solutions of ferric citrate and sodium phosphate, is perhaps a mixture of ferric phosphate and sodium citrate, or it is more probably a sodio-ferric citro-phosphate. When a dilute **mineral acid** other than metaphosphoric acid is added the sodium citrate or the sodio-ferric citro-phosphate is broken up and the ferric phosphate is precipitated. Strong mineral acids may redissolve the precipitate. Metaphosphoric (glacial phosphoric) acid free from orthophosphoric acid does not cause precipitation. 2. In aqueous solution the soluble phosphate of iron is precipitated by **sodium or potassium hydroxide** as ferric hydroxide. **Ammonium hydroxide** gives a reddish color, but no precipitate. [See FERRICUM and ACIDUM PHOSPHORICUM.]

**Ferri Pyrophosphas Solubilis.**—1. The soluble pyrophosphate of iron is a mixture or compound similar to the soluble phosphate of iron, and on adding a dilute **mineral acid** the ferric pyrophosphate is thrown out of solution. Strong solutions of mineral acids may redissolve the precipitate. Metaphosphoric acid free from orthophosphoric acid does not cause precipitation. 2. The red-brown ferric hydroxide is precipitated from aqueous solutions by **potassium or sodium hydroxide**. 3. **Ammonium hydroxide** turns the solution red, but does not

cause precipitation. [See FERRICUM and pyrophosphoric acid under ACIDUM PHOSPHORICUM.]

**Ferricum.**—1. Ferric salts are precipitated from their aqueous solutions by the alkali **hydroxides** and **carbonates** as the red-brown ferric hydroxide. This precipitation is more or less prevented by the presence of sugar, glycerin, citrates, tartrates, and other organic compounds. 2. When the insoluble carbonates of **barium**, **calcium**, **magnesium**, and **copper** are added to solution of ferric salts the ferric hydroxide is precipitated, the base added combining with the acid of the ferric salt. 3. **Borax** with solutions of ferric salts gives an insoluble basic borate (Watts, 1. 530). Sugar, glycerin, citrates, and tartrates prevent or retard precipitation. 4. Solutions of the **alkali phosphates** precipitate from neutral solutions of ferric salts the white ferric phosphate, the precipitation being prevented by citrates, tartrates, and considerable excess of free acids. 5. The **alkali sulphides** precipitate the black ferrous sulphide after reducing the ferric compounds to ferrous and liberating sulphur. **Hydrogen sulphide** reduces ferric to ferrous and liberates sulphur, but causes no precipitation of iron. 6. Soluble **cyanides** precipitate the neutral solutions of ferric salts as ferric hydroxide with evolution of hydrocyanic acid. 7. **Ferrocyanides** with ferric salts give the blue precipitate of ferric ferrocyanide (Prussian blue); this is prevented to some extent by citrates in neutral solutions. 8. **Ferricyanides** give a brown solution with ferric salts. 9. With solutions of ferric salts **sulphites** give a red solution of ferric sulphite, which changes on heating or standing to ferrous sulphate and the solution becomes nearly colorless. 10. **Phosphoric acid** in excess decolorizes a solution of ferric chloride by forming the colorless ferric phosphate. 11. In neutral solutions the alkali **hypophosphites** precipitate ferric salts as ferric hypophosphite, but in acid solutions the iron is reduced to the ferrous condition and the hypophosphite is oxidized to a phosphate. 12. **Hydriodic acid** and soluble **iodides** with a mineral acid reduce ferric compounds to ferrous, iodine being liberated

and precipitated if the iodide is entirely decomposed. 13. **Arsenites** give precipitates of basic ferric arsenite with solutions of ferric salts if they are not too strongly acid. The basic ferric arsenite is changed to some extent to a ferrous arsenate (P. & J., 62.) **Arsenates** give the insoluble ferric arsenate. 14. The official **tannic acid** gives a blue-black solution or precipitate of ferric tannate. Phosphoric acid in excess destroys the color by breaking up the compound and forming the colorless ferric phosphate. Some tannic acids give a green-black color. With the exception of gentian, quassia, columbo, American columbo, chiretta, and canella nearly all drugs contain tannin. 15. **Gallic acid** gives a blue-black color with a solution of ferric chloride. [See ACIDUM GALLICUM, No. 7.] 16. **Acetates** give a deep dull red liquid with nearly neutral solutions of ferric salts, due to the formation of ferric acetate. This solution on heating throws down a precipitate of basic ferric acetate. **Acetic acid** does not increase the color of a solution of ferric chloride unless the iron solution is quite highly diluted. 17. Soluble **benzoates** precipitate nearly neutral solutions of ferric salts as ferric benzoate which is flesh-colored. The presence of an excess of free acid or of alkali tartrate interferes or prevents the precipitation. 18. With solutions of the **salicylates** ferric salts give a blue-violet to violet-red solution; the color is destroyed by a large excess of a mineral acid. In concentrated or neutral solutions ferric salicylate may be precipitated. 19. **Carbolic acid** with concentrated solutions of ferric chloride gives but little increase in color. On diluting with water the solution becomes green and more water changes it to violet blue. 20. In dilute aqueous solutions **creosote** or **guaiacol** gives with ferric chloride a violet-blue color which soon changes to green brown. An alcoholic solution of ferric chloride with creosote gives blue green. 21. **Acetanilide** with an alcoholic solution of ferric chloride gives a red color. With an aqueous solution it gives no color unless heated, and then the color fades on cooling. If the solution is heated for several minutes the color is changed to

a permanent green. 22. **Antipyrine** gives a red color with a solution of a ferric salt. [See **ANTIPYRINA**, No. 3.] 23. **Phenacetin** with a tincture of ferric chloride gives a deep red solution. 24. With **pyrocatechin** a solution of ferric chloride gives a green color; 25. with **pyrogallol** it gives a red; 26. and with **resorcin**, a violet. 27. An alcoholic solution of **salol** gives a violet to red color with a tincture of iron, but when sufficient water is added the color is destroyed and the **salol** precipitated. 28. **Piperazine** gives a red-brown precipitate. 29. Oil of **wintergreen** gives a violet color with an alcoholic solution of ferric chloride; 30. oils of **cloves**, **bay**, and **pimenta** give a blue to a green; 31. oil of **cinnamon** gives a brown; 32. oil of **thyme** gives a green brown, changing to red. 33. An alcoholic solution of ferric chloride gives a dark brown-green color with **podophyllin**; 34. with **aloin** it gives a green black to a brown black; 35. with **benzoin**, a brown to green; 36. with **gamboge**, a black brown; 37. with **asafœtida** or **storax**, a green brown; 38. with **myrrh**, a red brown; 39. with **guaiac**, a blue to brown; 40. with **balsam of Peru**, a green black; 41. with **balsam of Tolu**, a brown; 42. and with **shellac**, a black. 43. With a nearly neutral aqueous solution of ferric chloride **morphine** gives a blue to green solution, and with **apomorphine** it gives a red changing to a black. 44. Solutions of ferric salts gelatinize mucilage of **acacia**. [See **ACACIA**, No. 2.] 45. They coagulate solutions of **albumin**. 46. **Glycerin** and **syrup** give a darker color due to hydrolysis into ferric hydroxide and hydrochloric acid (*Bul. Pharm.*, XIX. 389.)

**Ferrosus.**—1. Ferrous salts are quite quickly changed to basic ferric compounds on being exposed to the air. Sugar, glycerin, and organic matter in general retard the oxidation. 2. Ferrous salts in aqueous solution are precipitated to some extent by the **alkali hydroxides** as the white ferrous hydrate, quickly changing to the ferroso-ferric hydrate, which is of a dirty green to a black color. This precipitate ultimately oxidizes to a ferric hydroxide or oxide. Ammonium chloride of sulphate, soluble citrates or tartrates, sugar,

glycerin and many organic compounds, dissolve the ferrous hydrate or prevent the precipitation. 3. The soluble **carbonates** precipitate the ferrous carbonate, white if purely ferrous, but quickly becoming green and ultimately brown, due to the formation of a ferric compound. 4. The soluble **phosphates** precipitate the white or bluish-white ferrous phosphate. 5. With nearly neutral solutions **borax** gives a white precipitate. 6. The soluble **sulphides** (not hydrogen sulphide) precipitate the black ferrous sulphide. 7. **Ferrocyanides** precipitate the light blue ferrous ferrocyanide. 8. **Ferricyanides** precipitate the dark blue ferrous ferricyanide. 9. **Arsenites** and **arsenates** give precipitates with solutions of ferrous salts (P. & J., 158). 10. **Tannic acid** with strong solutions of ferrous salts precipitates the white gelatinous ferrous tannate. This quickly oxidizes, forming the nearly black ferric tannate. Ferrous salts usually contain enough of a ferric salt to give the dark color at once. 11. **Gallic acid** with a concentrated solution of a ferrous salt gives a white precipitate which soon turns dark, due to the oxidation of the iron and formation of the ferric gallate. 12. Ferrous salts in solution are oxidized to ferric compounds by salts of **gold** or **silver**, by **hydrogen dioxide**, **chromates**, **permanganates**, **nitrous** or **nitric acid**, **chlorine** or **chlorates** in acid solution, **bromine** or **bromates** in acid solution, **iodates** in acid mixture, **mercuric compounds** in alkaline mixture, **arsenates** in alkaline mixtures, and by oxygen of the **air**. 13. The **alkaline citrates** in solution modify the astringent effects of ferrous salts, and dissolve many of the salts not soluble in water.

**Ferrum Reductum.**—1. Reduced iron combines with **acids** to form salts. 2. It is oxidized by moist **air**. 3. In the presence of water it reduces to the metallic condition salts of **copper**, **bismuth**, **lead**, **silver**, **mercury**, and **antimony**. 4. Triturated dry with strong oxidizing agents, such as **potassium permanganate** or **potassium chlorate**, it is liable to cause an explosion. 5. In the presence of water iron forms ferrous iodide with **iodine**, and ferrous bromide with **bromine**.

6. Iron is slowly oxidized to a hydroxide by **hydrogen dioxide** water.

**Fluidextracti.**—1. Fluidextracts are generally more or less acid and liberate carbon dioxide from **carbonates**. 2. **Water** causes precipitation of inert matter and sometimes active principles.

**Gelatinum.**—1. Solutions of gelatin are coagulated by **tannic acid**, **picric acid**, **metaphosphoric acid**, **chlorine water**, **mercuric chloride**, **platinum chloride**, **alumnol**, **alcohol**, or **formaldehyde**. Aqueous solutions are not precipitated by **alum**, **lead acetate**, **ferric chloride**, **dilute acids**, or **dilute alkalis** (N. S. D., 710). 2. **Heating** an aqueous solution of gelatin for some time renders it incapable of gelatinizing.

**Glucosides.**—1. Glucosides are decomposed by prolonged contact with **mineral acids**, **alkalies**, **hot water**, or **ferments**. Some glucosides may be decomposed by one of these agents, others by two or more of them. One of the products formed is **glucose**. 2. **Tannic acid** or **lead subacetate** generally precipitates the glucosides from their aqueous solutions. 3. The glucosides are not usually precipitated by the **alkali hydroxides** or **carbonates** or **general alkaloidal reagents**. 4. Many of them give color reactions resembling those produced by the **alkaloids**.

**Glycerinophosphates.**—1. The **glycerinophosphates** are easily decomposed and are preferably given alone. Those of the **alkalies** may give no precipitate when decomposed, but those of the other metals will have the incompatibilities of the bases. 2. **Citric acid** increases the solubilities.

**Glycerinum.**—1. Glycerin with **borax** forms **glycerol borate** and **sodium metaborate**. The **glycerol borate** is decomposed by **water**, forming **boric acid** and **glycerin**. In consequence of the formation of free acid, this mixture is incompatible with **carbonates**, but generally compatible with solutions of **alkaloidal salts** where **borax** alone would cause a precipitation. **Glucose**, **honey**, and some other organic compounds act like **glycerin**. 2. Strong **nitric acid** mixed with concentrated **sulphuric acid** converts **glycerin** into the explo-

sive nitroglycerin. When glycerin is carefully treated with nitric acid, it is converted into a mixture of oxalic acid, glyceric acid, and other organic acids (Allen, II. 304). Warming glycerin with dilute nitric acid may cause a violent reaction. 3. Gently heated with solid **potassium hydroxide** glycerin is converted into potassium acetate and formate (Allen, II. 304). 4. In dilute solutions **potassium permanganate** changes glycerin to formic, propionic, and tartronic acids (M. & M., II. 618). In a strongly alkaline solution oxalic acid and carbon dioxide are formed (Allen, II. 304). Manganese dioxide is precipitated. 5. Oxidizing agents, as **chromates**, **chlorinated lime**, **nitrohydrochloric acid**, **hydrogen dioxide**, or **manganese dioxide** with hydrochloric acid, convert glycerin into oxalic acid and carbon dioxide. When glycerin is rubbed with the dry **oxidizing agents** explosion is liable to take place. 6. Concentrated **sulphuric acid** with glycerin forms acrolein. 7. Glycerin may be made to combine with several organic and inorganic **acids**. (U. S. D., 588). 8. Glycerin unites with **alkalies** and **alkaline earths** to form compounds soluble in water, the former also soluble in alcohol, the latter not precipitated by carbon dioxide (N. S. D., 725). 9. Glycerin prevents to some extent the precipitation, by alkali hydroxides and carbonates, of solutions of salts of **lead**, **copper**, **antimony**, **aluminum**, **chromium**, **iron**, **zinc**, and **magnesium**. 10. It dissolves most deliquescent salts and increases the solubility of many inorganic and organic salts. 11. Glycerin sometimes precipitates **alkaloidal salts** from their aqueous or acidulated solutions (U. S. D. 588). 12. With most **fixed oils** it does not mix to form clear solutions. 13. Glycerin is sometimes contaminated with iron from the container, and this may give a color with carbolic acid, tannic acid, and other substances.

**Glyceritum Boroglycerini.**—Glycerite of boroglycerin is decomposed by **water** and the boric acid liberated may be precipitated.

**Glycerylis Trinitras.**—1. Nitroglycerin explodes violently on **percussion**. 2. When impure it gradually decomposes, forming glyceric, oxalic, and nitrous acids, and the gases formed may burst the container (M. & M., II. 619). 3. **Alkalies** or their **carbonates** decompose it when dissolved in alcohol, forming a nitrite, nitrate, acetate, oxalate, and formate (Allen, II. part. I. 333). Alkalies convert it into glycerin and a nitrate of the base (Richter, I. 474).

**Glycyrrhizinum Ammoniatum.**—1. Ammoniated glycyrrhizin in aqueous solution is decomposed and the glycyrrhizic acid precipitated by **mineral acids**; the taste is changed from sweet to somewhat bitter. 2. With solutions of salts of many of the **heavy metals** it gives voluminous precipitates (N. D., 734). 3. **Fixed alkalies** liberate ammonia from it.

**Guaiacolis Carbonas, Duotal.**—1. Guaiacol carbonate is decomposed by **alkali hydroxides**, forming a carbonate and guaiacol. 2. With tincture **ferric chloride** it does not give the guaiacol color. 3. Rubbed with **chloral hydrate** it slowly gives a mass.

**Guaiacolum.**—1. The incompatibilities of guaiacol are similar to creosote. [See CREOSOTUM.] 2. It combines with some **acids** to form crystalline compounds. 3. With **ferric chloride** it gives at first a blue color, changing to green on adding more ferric chloride. 4. It reduces a few salts, as **gold chloride** and **silver nitrate**, to the metallic condition.

**Guaiacum.**—1. An alcoholic solution of the fresh resin of guaiac is colored blue by **nitric acid**, **chromic acid**, **chlorine**, **potassium ferricyanide**, **potassium permanganate**, **ferric chloride**, **gold chloride**, **ozone**, **spirit of nitrous ether**, and other **oxidizing agents**. This is due to the action on the guaiaconic acid. With an excess of the oxidizing agent the color is changed to green and then red. Continued exposure to light or heat deprives the guaiac of the property of being colored blue by oxidizing agents, and causes the resin to turn green. 2. It dissolves in a solution of **potas-**

**sium** or **sodium hydroxide**, forming unstable compounds which are decomposed by diluting with water (N. S. D., 744).

3. **Sulphuric acid** dissolves it, forming a red solution with a tinge of blue. 4. Either in substance or in tincture, guaiac gives a blue color with mucilage of **acacia**. [See ACACIA, No. 15.]

**Helmitol**.—1. It is decomposed by **acids** and **alkalies**, liberating formaldehyde.

**Heroine Hydrochloridum**.—1. Heroine hydrochloride acts much like morphine hydrochloride and is quite easily decomposed by **acids** and **alkalies** forming morphine. 2. **Alkali hydroxides** and **carbonates** precipitate the base from aqueous solutions of the salt. 3. It is usually precipitated by the general **alkaloidal reagents**, though not always in dilute solutions. 4. It lessens the fluorescence of **quinine sulphate**. 5. It reduces **potassium permanganate**. 6. **Apomorphine** is said to be incompatible with it.

**Hexamethylenamina, Urotropine**.—1. Hot **water** decomposes it. 2. Warming with dilute **sulphuric acid** liberates formaldehyde. 3. An aqueous solution is precipitated by **mercuric chloride** or **tannic acid**, if the solution is not too dilute.

**Holocainæ Hydrochloridum**.—1. An aqueous solution is precipitated by **alkali hydroxides** and **carbonates** and by **chromic acid** (N. S. D., 579). 2. It is precipitated from a water solution by many of the **alkaloidal reagents**. 3. The addition of **sodium hypochlorite** to a solution gives a flesh color, with the separation of a violet precipitate.

**Homatropina**.—The incompatibilities are similar to those of atropine. [See ATROPINA.]

**Hydrargyri Chloridum Corrosivum**.—1. Mercuric chloride in aqueous solution is slowly and partly changed to hydrochloric acid and calomel, which change is prevented by ammonium chloride or hydrochloric acid (N. S. D., 769). 2. It is precipitated by solutions of **fixed alkali hydroxides** or **lime water**. The precipitate is the orange-yellow mercuric oxide if the hydroxide is in excess, or if the mercuric salt is in excess

it will be the red-brown basic chloride of mercury. The precipitation is prevented to some extent by the presence of citrates, tartarates, glycerin, sugar, and acacia although there may form a steel-gray precipitate in a few days. 3. **Ammonium hydronide** gives the "white precipitate," or "ammoniated mercury," mercurammonium chloride. 4. **Ammonium carbonate** acts like ammonium hydroxide. 5. **Potassium carbonate** or **sodium carbonate** precipitates solutions of mercuric chloride as the red-brown oxychloride, which by excess of the carbonate with heat is converted into the yellow mercuric oxide. Citrates, tartrates, glycerin, acacia, and sugar prevent the precipitation to some extent. 6. A solution of mercuric chloride with **sodium** or **potassium bicarbonate** gives an effervescence and a white precipitate. If the mercuric salt is in excess the precipitate turns to a purplish red in a few hours. If the bicarbonate is in excess the precipitate remains white for some time but may ultimately change to the purplish red. Various oxychlorides are formed (M. & M., III. 217). 7. **Borax** precipitates the red-brown basic mercuric chloride (Watts, I. 641). 8. **Hydrogen sulphide** and the **alkali sulphides** with solutions of mercuric chloride give mercuric sulphide. The precipitate first formed is white and consists of the union of mercuric chloride and mercuric sulphide; by further addition of the precipitating agent the black mercuric sulphide is formed. 9. The soluble **iodides** precipitate solutions of mercuric chloride as mercuric iodide, first reddish yellow, becoming red. This precipitate dissolves in excess of the soluble iodide or excess of mercuric chloride, forming double compounds. If potassium iodide has been used in excess, the double compound is approximately represented by the formula  $(KI)_2HgI_2$ . A solution of this double salt is known as "Mayer's reagent" and precipitates nearly all alkaloids from solutions of their salts; the presence of alcohol prevents this precipitation to some extent. 10. The soluble **bromides** precipitate from concentrated solutions of mercuric salts the white mercuric

bromide, which is soluble in excess of the soluble bromide or in excess of the mercuric salt (P. & J., 42). Ordinarily no trouble is experienced in combining these. 11. Soluble **phosphates** precipitate from neutral solutions of mercuric chloride the white mercuric phosphate. 12. Mercuric chloride combines with the **chlorides** of the alkalies to form double compounds, which are more soluble in water than mercuric chloride. 13. **Hypophosphorus acid** and **hypophosphites** reduce mercuric chloride to mercurous chloride and finally to metallic mercury. 14. **Sulphurous acid** and soluble **sulphites** reduce mercuric chloride to mercurous chloride. 15. **Thiosulphates** added to a solution of mercuric chloride give a white precipitate, then yellow, then black. The black precipitate is sulphide of mercury. 16. Mercuric chloride is reduced by metallic **copper, zinc, or iron**, in the presence of water, to calomel, and then metallic mercury. 17. **Arsenites** in alkaline mixtures reduce mercuric chloride to calomel and then metallic mercury, and are changed to arsenates. 18. **Tartar emetic** reduces corrosive sublimate and precipitates it as calomel; in alkaline mixtures metallic mercury is formed. 19. **Ferrous compounds** in alkaline mixtures with mercuric compounds are oxidized to ferric compounds, and reduce mercuric to mercurous. 20. **Alcohol** slowly reduces mercuric chloride to calomel (M. & M., I. 98). 21. According to some writers corrosive sublimate is slowly reduced to calomel by **compound syrup of sarsaparilla** and by **honey** but not by pure syrup; the precipitation is retarded by sodium chloride (U. S. D., 619). 22. A solution of **albumin** is coagulated by mercuric chloride; this is prevented by the presence of sodium or ammonium chloride. 23. Mercuric chloride precipitates from concentrated aqueous solutions nearly all **alkaloidal salts**, some **neutral** and **bitter principles**, some **glucosides**, **antipyrine**, **piperazine**, **tannic acid**, **vegetable extractive matter**, and **gelatin**. 24. **Sugar, gum, fats, and resins** slowly decompose it, precipitating calomel; heat and light hasten the reaction (N. S. D., 770). 25. **Camphor** increases the solubility of mercuric chloride in alcohol or ether.

**Hydrargyri Chloridum Mite.**—1. Calomel is changed to the black mercurous oxide by a solution of the **hydroxides** of **potassium, sodium, calcium, or barium**. 2. Solutions of the **carbonates** of the **fixed alkalies** convert calomel into a black mass, which is probably a mixture of the basic carbonate and oxide. 3. Calomel with **ammonia water** forms a black mixture of metallic mercury and mercuric ammonium chloride,  $\text{NH}_2\text{HgCl}$  (P. & J., 39). **Ammonium carbonate** acts like ammonia water. 5. The soluble **iodides** in the presence of water convert calomel into yellow mercurous iodide, which is further decomposed by an excess of the soluble iodide, forming metallic mercury and mercuric iodide. This mercuric iodide combines with the soluble iodide to form a double compound which is soluble in water. The presence of a little metallic mercury gives a green color with mercurous iodide. The color becomes more gray or black as the proportion of metallic mercury increases and the mercurous iodide decreases. 6. Soluble **bromides** act similarly to soluble iodides. 7. According to M. Mialhe, calomel is in part converted into corrosive sublimate and metallic mercury by **ammonium, potassium, or sodium chloride** at the temperature of the body (U. S. D., 625). A number of other experimenters call attention to the decomposition. (See Watts, III. 896. D. C., XLIII. 176. Proceedings Kansas Pharm. Assoc. for 1897.) The change seems to be more marked in the presence of gastric juice or pancreatin. O. H. Tansy (in Pharm. Rundschau) has made experiments to prove the fallacy of the belief that sodium chloride and calomel are incompatible. Diekman (in Ph. Era, XXII. 7) made experiments showing that the amount of mercuric chloride formed in the test tube is not over six tenths per cent. of the calomel taken, and consequently not enough to explain the increased action which the mixture sometimes seems to have. Prof. Pouchet claims that if sodium chloride is capable of converting calomel then it will be necessary to eliminate all of the sodium chloride in the system before giving a dose of calomel. Numerous other experimenters

lend their support to the belief that no change, or but very little, takes place, and some bring forward clinical results to prove their point. One writer says that the exaggeration of the toxic effect of calomel, after ingestion of salt or organic acids, arises from the fact that its combination with albuminoid substances in the stomach is facilitated and will yield products much more soluble, so that calomel will be absorbed in larger amounts.

8. **Hydrocyanic acid** and soluble **cyanides** in aqueous solution convert calomel into metallic mercury and mercuric cyanide and chloride.

9. **Bicarbonate of sodium** with calomel is said to produce corrosive sublimate very slowly. Whether any change takes place or not, calomel is more frequently given with sodium bicarbonate than without it.

10. Calomel with **alkali sulphites** in solution separates metallic mercury, and a double sulphite of the alkali and mercury goes into solution (M. & M., III. 216).

11. Solutions of **hydrogen sulphide** or **alkali sulphides** convert calomel into the black mercurous sulphide.

12. **Iodine** changes calomel into mercuric chloride and mercuric iodide in the presence of water or alcohol.

13. A mixture of **iodoform** and calomel exposed to light gives red mercuric iodide and the odor of iodoform is lost.

14. Exposed to **sunlight** calomel darkens, due to the separation of metallic mercury; mercuric chloride is also formed.

15. Calomel is said to be changed to metallic mercury and mercuric chloride by heavy trituration.

16. Boiling **hydrochloric acid** converts calomel into mercuric chloride and metallic mercury; if dilute hydrochloric acid is used, no metallic mercury will be separated (M. & M., III. 216).

17. Calomel is reduced to metallic mercury by **nitrous acid**, **spirit of nitrous ether**, **hypophosphorous acid**, and in alkaline mixtures by **arsenites** and **tartar emetic**.

18. Mercurous chloride is oxidized to mercuric compounds by **nitric** and **nitrohydrochloric acids**, **chlorine**, **bromine**, **iodine**, **hydrogen dioxide** (slowly), and in alkaline mixtures by **silver salts**.

19. Calomel reacts with the iodine in iodine compounds like **airol**, **aristol**, **europhen**, and **iodoform**.

20. Soap is gen-

erally alkaline and darkens calomel, probably forming an oxide. 21. Calomel in the presence of moisture is darkened by certain alkaloids, such as **cocaine** or **pilocarpine**. The darkening is due to the formation of metallic mercury, while at the same time some mercuric chloride is formed, which combines with the alkaloid. 21. Calomel is slowly turned dark in the presence of moisture by **antipyrine**, but at once when sodium bicarbonate is mixed with it. Metallic mercury and a mercuric compound is formed. 22. Calomel is said to be changed to metallic mercury and mercuric chloride by **cane-sugar** even in the absence of moisture. Considerable time is required for the change. **Milk-sugar** gives the reaction more quickly. **Acacia** and **tragacanth** have similar properties but in a less degree.

**Hydrargyri Cyanidum.**—Mercuric cyanide, so far as the base is concerned, has incompatibilities similar to mercuric chloride, except that aqueous solutions are not precipitated by alkali hydroxides or iodides on account of the formation of soluble double compounds. [See **HYDRARGYRI CHLORIDUM CORROSIVUM** and **ACIDUM HYDROCYANICUM**.]

**Hydrargyri Iodidum Flavum.**—1. Mercurous iodide is rapidly darkened by the **light**, particularly in the presence of **moisture**. The darkening is in proportion to the decomposition into mercuric iodide and mercury. 2. With solutions of **iodides** mercurous iodide is decomposed, forming mercuric iodide and mercury. [See **HYDRARGYRI CHLORIDUM MITE**, No. 5.] 3. **Ammonia water** converts it into mercuric iodide and metallic mercury (P. & J., 42). 4. Mercurous iodide is reduced and oxidized by the same reagents that reduce and oxidize calomel.

**Hydrargyri Iodidum Rubrum.**—1. Mercuric iodide is decomposed by solutions of fixed **alkali hydroxides** forming the yellow mercuric oxide and a soluble double iodide of the alkali and mercury. 2. **Lime**, **sodium carbonate**, and **potassium carbonate** do not decompose mercuric iodide in the presence of water, but do in the presence of alcohol (M. & M., III. 220). 3. With soluble **iodides** it forms solu-

ble double compounds. 4. The incompatibilities are quite similar to those of mercuric chloride. 5. Mercuric iodide is soluble in a solution of sodium thiosulphate, potassium chloride, and many ammonium salts.

**Hydrargyri Oxidum Flavum.**—1. Mercuric oxide combines with most **acids** to form salts. 2. With **mercuric chloride** in solution it forms the red-brown oxychloride. 3. Mercuric oxide darkens in the **light**, forming mercury and oxygen (M. & M., III. 222) or mercurous oxide (N. S. D., 779). 4. Mercuric oxide precipitates bases from solutions of their chlorides but not from oxyalts (M. & M., III. 909). 5. It is reduced by many substances as gums, sugar, and lard (N. S. D., 780).

**Hydrargyri Subsulphas Flavus.**—1. Turpeth mineral dissolves readily in **sulphuric**, **nitric**, or **hydrochloric acid**. 2. Solutions of **fixed alkali hydroxides** decompose turpeth mineral, forming mercuric oxide and the sulphate of the alkali.

**Hydrargyrum Ammoniatum.**—1. White precipitate is decomposed by solutions of the **fixed alkali hydroxides** or **lime water**, liberating ammonia and forming the yellow mercurous-ammonium chloride (M. & M., III. 208). 2. **Water** decomposes it slowly, forming mercurous-ammonium chloride and ammonium chloride (M. & M., III. 208). 3. When ammoniated mercury is triturated with **iodine**, the mixture will puff up after a time from the spontaneous decomposition of nitrogen iodide formed in it; but in the presence of alcohol the decomposition takes place suddenly and with violent explosion (N. D., 788). 4. **Bromine** or **chlorine** causes the evolution of hydrogen and the formation of mercuric bromide or mercuric chloride (M. & M., III. 208). 5. Ammoniated mercury is dissolved by a solution of **sodium thiosulphate** in the cold, evolving ammonia; if heat is applied mercuric sulphide is formed (N. D., 788).

**Hydrargyrum Colloidale, Hyrgol.**—1. Colloidal mercury in aqueous solution turns silver-gray on **heating** (N. S. D.,

787). 2. The metal is precipitated by **acids, bases, salts** of many metals. **Albumin** is not precipitated and tends to prevent the precipitations noted above. 3. Reducible metallic chlorides, as mercuric chloride, are reduced. **Calomel** thus formed remains in solution if the solutions are dilute. 4. **Trituration** tends to transform it into the insoluble form.

**Hydroquinone.**—1. Hydroquinone is oxidized to quinone by **ferric chloride, chlorine, dilute nitric acid, and chromic acid** (M. & M., II. 730). 2. Strong **nitric acid** oxidizes it to oxalic acid (M. & M., II. 730). 3. An aqueous solution turns brown in the **air**, more quickly in the presence of an alkali. 4. A strong aqueous solution is precipitated by **ferric chloride**, soluble in excess of the latter (M. & M., II. 730).

**Hyoscyamina.**—1. Hyoscyamine is converted into atropine by **heating** to 248° F., or above its melting point, for five or six hours. 2. It is not precipitated by bicarbonates or ammonium carbonate, except from concentrated solutions. 3. It is easily decomposed by warming with **alkalies** or **water**. 4. It has about the same incompatibilities as atropine. [See ATROPINA.]

**Ichthyolum.**—1. **Acids** combine with the ammonia and precipitate the ichthyolsulphonic acid as a dark resinous mass which adheres to the sides of the vessel, unless the acid be quite dilute. 2. Alkaline **hydroxides** or **carbonates** liberate ammonia. 3. **Ferric salts** in solution with ichthyol form compounds of iron and ichthyol, while at the same time a partial oxidation of ichthyol is brought about by the ferric salt. **Ferrous salts** precipitate the sulpho-ichthyolate of iron (Am. D., XXVII. 364). 4. Ichthyol gives precipitates with solutions of many **metallic salts** as ichthyolsulphonates; some of the salts that give precipitates are alum, ammonium bromide, ammonium chloride, magnesium sulphate, potassium bromide, potassium iodide, sodium chloride, and zinc sulphate. 5. **Mercuric chloride** does not give a precipitate at once but does on standing and is reduced to calomel (M. R., x. 284). 6. Solid **iodine** gives a

black mixture. Tincture of iodine gives no precipitate with a dilute solution but makes it much darker. Iodine with ichthyol and petrolatum gives a blue and then a green-black color. 7. It combines with **formaldehyde** to give ichthoform. 8. With **albumin** it gives ichthyol albuminate (ichthalbin). 9. It precipitates some **alkaloidal salts** only in concentrated solution and some only in dilute solution (M. R., x. 284). The precipitate is sticky. 10. **Hydrogen dioxide** destroys the odor. 11. Rubbed with **ammonium chloride** it gives a stiff mass and some effervescence can be seen. 12. **Alcohol** gives a precipitate but ichthyol is said to be soluble in a mixture of alcohol and ether. 13. Triturating with crystallized **phenol**, ichthyol is made thinner. 14. It has the property of making some insoluble substances soluble in water, e.g., eucalyptol, creosote, camphor, guaiacol, oils of peppermint, wintergreen, and turpentine (D. C., XLVIII. 65).

**Infusa.**—1. Infusions and decoctions generally contain some tannic acid, albuminous and extractive matters, which are precipitated by many of the metallic salts, such as **mercuric chloride**, **lead acetate**, **silver nitrate**, **tartar emetic**, or **ferric chloride**. 2. When the tannic acid is present in considerable amount they are incompatible with **alkaloidal salts**, because of the formation of the insoluble alkaloidal tannate. 3. Many of the infusions and decoctions are decolorized by a solution of **lead subacetate** or by **aluminum hydroxide**. 4. They should not be mixed with alcoholic solutions of substances insoluble in water.

**Iodates.**—1. Iodates sometimes occur as impurities in iodides, and in such cases they liberate iodine when brought in contact with **acids**. 2. Iodates in solution with a dilute mineral acid are reduced to iodine by **hypophosphites**, **iodides**, **bromides**, **nitrites**, **arsenous acid**, **ferrous compounds**, and **morphine**.

**Iodoform.**—1. Iodoform heated with a solution of an **alkali hydroxide** gives an iodide and a formate. 2. **Silver nitrate** in solution decomposes iodoform, producing silver

iodide, nitric acid, and carbon monoxide (M. & M., III. 33). Triturated dry with silver nitrate, violent reaction takes place with the formation of silver iodide, carbon dioxide, and nitrogen tetroxide (Ph. E., VIII. 302). 3. The color of a mixture of **calomel** and iodoform is yellow, but when it is exposed to light the color changes to red, due to the formation of the red iodide of mercury. Perhaps some chloroform is also produced. 4. When gently heated with yellow **mercuric oxide** iodoform is decomposed, giving carbon monoxide, formic acid, mercuric iodide, and water (M. & M., III. 33). 5. Exposed to direct **sunlight**, iodoform is completely oxidized by the **air**, forming carbon dioxide, iodine, and water (M. & M., III. 33). 6. Iodoform in solution or mixed with a **fatty substance** decomposes in the light, forming iodine and methyl iodide (M. & M., III. 33). For a time the iodine will be taken up by the fatty matter (unless it is petrolatum), forming colorless addition products (M. R., IX. 114). 7. Iodoform with **hydrogen dioxide water** seems not to be readily affected, but when in solution with ether hydrogen dioxide liberates iodine. 8. **Tannin** slowly deodorizes and decomposes iodoform. 9. **Balsam of Peru** deodorizes it and forms a compound with it (U. S. D., 662).

**Iodolum.**—1. Iodol remains unchanged when heated below 100° C. (N. S. D., 822). 2. Oxidizing agents liberate iodine. 3. It should not be given with agents having a strong affinity for iodine.

**Iodophenacetin, Iodophinin.**—1. **Water** decomposes iodophenacetin, liberating iodine (M. R., IV. 359). 2. **Alkalies** abstract iodine, regenerating phenacetin (M. R., IV. 359). 3. It should not be mixed with substances having a strong affinity for iodine.

**Iodum.**—1. In aqueous solution fixed **alkali hydroxides** or **carbonates** decolorize iodine, forming soluble iodides and iodates. 2. Iodine with **ammonia water** slowly becomes colorless, forming chiefly ammonium iodide, with some ammonium iodate. There is a liability of

there being precipitated a dark-brown powder, the "iodide of nitrogen," which when dry is easily and violently explosive. Explosive compounds of nitrogen and iodine may also be formed by mixing alcoholic solutions of ammonia and iodine; by adding a solution of chlorinated lime (neutralized by acetic acid) to an aqueous solution of ammonium iodide; by adding ammonia to a mixture of hydrochloric acid and iodic acid; by the action of nitrogen chloride on an aqueous solution of potassium iodide; or by adding an alcoholic solution of iodine to ammoniated mercury. Analyses of the products of these reactions seem to show that at least three different explosive compounds are formed, differing in the number of hydrogen atoms replaced by the iodine (M. & M., III. 560).

3. **Nitric acid** slowly oxidizes iodine to iodic acid.
4. **Hypophosphites** are changed to phosphates, and the iodine is reduced to an iodide.
5. **Hydrogen sulphide** forms hydriodic acid and sulphur.
6. **Thiosulphates** form sulphates and an iodide.
7. **Sulphites** form sulphates and an iodide.
8. **Chlorine** forms iodic and hydrochloric acids, and in the presence of potassium hydroxide a periodate.
9. **Chlorates** in the presence of an acid form chlorides and iodic acid.
10. **Bromine** in the presence of an alkali hydroxide forms a bromide and an iodate.
11. Iodine changes **mercurous compounds** either in acid or alkaline mixtures to mercuric compounds, and the iodine is reduced to an iodide.
12. Iodine combines directly with metallic **mercury**, forming mercurous iodide and then mercuric iodide.
13. Iodine with **ammoniated mercury** sometimes forms the explosive iodide of nitrogen.
14. In the presence of water iodine combines with metallic **iron** to form ferrous iodide.
15. In the presence of an alkali iodine changes **ferrous compound** to ferric and **antimonious** to antimonie.
16. **Arsenous compounds** are changed to arsenic by iodine in the presence of an alkali.
17. Iodine with **lime** and water forms a bleaching mixture.
18. Iodine combines with most metals and with many non-metals, such as **chlorine**,

**bromine, phosphorus, or arsenic.** 19. With iodine in a concentrated solution **potassium cyanide** forms potassium iodide and iodide of cyanogen (M. & M., II. 342). 20. Iodine reacts with **tannic acid** and water. [See ACIDUM TANNICUM, No. 12.] 21. Iodine when heated with **camphor** gives hydriodic acid, cymene, carvacrol, laurine, and other bodies (R. & S., III., part V. 427). 22. Iodine with **alcohol** heated with a fixed alkali yields iodoform. 23. **Methyl alcohol** is slowly oxidized by iodine to formaldehyde and formic acid. 24. Equal proportions of **resorcin** and iodine make a preparation soluble in water and devoid of caustic effect. 25. **Starch** and preparations containing it are turned blue by iodine. By warming the iodized starch, the color is destroyed, but on cooling it again assumes its blue color (P. & J., 350). 26. Iodine bleaches **litmus** and other vegetable colors. 27. It combines with many of the **fixed oils** to form additive compounds. 28. It combines with many **volatile oils**, and in some cases, as with turpentine, it acts with almost explosive violence. 29. In solution iodine slowly forms hydriodic acid. 30. Iodine, either in alcoholic solution or dissolved in an aqueous solution of potassium iodide, precipitates nearly all **alkaloids** from aqueous solutions of their salts. A large amount of alcohol present may prevent the precipitation. The precipitates from water are generally red brown and amorphous. Caffeine and theobromine in dilute solutions are not precipitated by iodine.

**Lactophenin, Phenetidin lactate.**—1. Lactophenin is decomposed by **acids** and **alkalies**. 2. An alcoholic solution gives a brown-red color with **ferric chloride**.

**Liquor Acidi Arsenosi.**—This solution contains free arsenous and hydrochloric acids. [See ACIDUM ARSENOSUM and ACIDUM HYDROCHLORICUM.]

**Liquor Ammonii Acetatis.**—Solution of ammonium acetate sometimes contains ammonium carbonate or free acetic acid. [See CARBONATES, AMMONIUM, and ACIDUM ACETICUM.]

**Liquor Arseni et Hydrargyri Iodidi.**—1. Dono-

van's solution liberates iodine on exposure to **air**. It has been suggested to keep a globule of mercury in it to prevent this change. 2. It precipitates nearly all **alkaloids** from aqueous solutions of their salts. 3. **Alkali hydroxides** precipitate the mercury as the oxide. 4. **Silver nitrate** is precipitated as silver iodide. [See HYDRARGYRI CHLORIDUM CORROSIVUM, ARSENI TRIONIDI and ACIDUM HYDRIODICUM.]

**Liquor Benzosulphinidi.**—1. Solution of saccharin contains some sodium bicarbonate which gives precipitates with many alkaloidal and metallic salts.

**Liquor Calcis.**—1. Lime water forms insoluble compounds with **tannic, tartaric, gallic, citric** and **oxalic acids**. The compounds are generally more soluble in cold water than in hot. 2. **Heat** tends to throw the calcium hydroxide out of solution. 3. Lime water has all of the incompatibilities of the fixed alkali hydroxides and of the calcium salts. [See LIQUOR POTASSII HYDROXIDI and CALCIUM.]

**Liquor Chlorig Compositi.**—1. Compound chlorine solution contains a little potassium chloride in addition to the chlorine. [See CHLORUM and ACIDUM HYDROCHLORICUM.]

**Liquor Ferri Dialysati.**—1. Many organic acids, the **alkali hydroxides** and **carbonates**, some **salts**, and **acacia** precipitate or gelatinize the solution of dialysed iron. 2. It combines with **Fowler's solution**, precipitating the arsenic combined with ferric hydroxide.

**Liquor Formaldehydi, Formalin.**—1. Formic aldehyde in solution slowly deposits the solid crystalline paraformaldehyde which is a condensation product, consisting of three molecules of formaldehyde and which is decomposed by high heat changing back to formaldehyde. It is slowly oxidized to formic acid (N. S. D., 901). 2. Formic aldehyde with dilute solutions of the hydrates of the **fixed alkalies** and **alkaline earths** is converted into methylenitan and formose (Richter, 192). Alkalies convert formaldehyde into methyl alcohol and a formate of the base (Wade, 73). Formaldehyde neutralizes alkalies but does not form true salts (W. D., XXI. 109). 3. **Ammonia**

unites to form hexamethyleneamine. 4. **Hydrogen dioxide water** or **iodine** oxidizes formic aldehyde to formic acid. 5. Formaldehyde is a strong reducing agent, reducing salts of gold and alkaline solutions of salts of **silver** and **copper**. 6. It enters into direct combination with albumin, casein, gelatin, agar-agar, starch, acids, and alkali hydroxides (N. S. D., 902).

**Liquor Plumbi Subacetatis.**—1. Goulard's extract is alkaline to litmus. 2. It is precipitated by nearly all **organic acids**, except formic, butyric, acetic, and lactic acids. 3. It precipitates from aqueous solutions nearly all **alkaloids**, **glucosides**, and **neutral principles**. 4. It precipitates **albumin** and **soap**. 5. **Mucilage of acacia** is gelatinized by a solution of lead subacetate, but when both are diluted with water stringy masses are formed. 6. Lead subacetate precipitates concentrated solutions of **antipyrine**. 7. A solution of phenol gives a precipitate with it. This can be prevented by glycerin or considerable dilution with water. 8. It unites readily with liquid or solid **fats** (N. D., 910), making emulsions. 9. Lead subacetate has all of the incompatibilities of lead acetate. [See PLUMBI ACETAS.]

**Liquor Potassii Arsenitis.**—1. Fowler's solution is alkaline, and contains some potassium bicarbonate which has been more or less changed to potassium carbonate. It consequently has the incompatibilities of a carbonate as well as those of a soluble arsenite. [See CARBONATES and ARSENI TRIOXIDUM.]

**Liquor Potassii Hydroxidi.**—1. Solutions of potassium hydroxide and sodium hydroxide have practically the same incompatibilities. In aqueous solution they combine with **acids** to form salts. 2. Exposed to the **air** they absorb carbon dioxide. 3. In the presence of water and heat they liberate **ammonium** from its compounds. 4. They precipitate solutions of salts of nearly all other common **metals** except arsenic, and the precipitate is a hydroxide, except in case of silver, mercury, and antimony, in which cases it is an oxide. The precipitation is prevented or hindered with salts of **mercury**, **lead**,

**copper, antimony, aluminum, chromium, iron, zinc, and calcium**, by the presence of sugar, glycerin, acacia, citrates, tartrates, and other organic substances. 5. **Calomel** is turned black, due to the formation of mercurous oxide. 6. **Gallic acid** combines with the hydrates, forming compounds that vary in color from a green to a yellow or brown. [See **ACIDUM GALLICUM**, Nos. 1 and 2.] 7. **Tannic acid** combines with the hydroxides, giving various colors on standing. [See **ACIDUM TANNICUM**, No. 2.] 8. Potassium hydroxide with a concentrated solution of **tartaric acid** gives a precipitate of cream of tartar. 9. **Chloral hydrate** is decomposed by the alkali hydroxides, giving chloroform and a formate of the base. 10. The alkali hydroxides precipitate nearly all of the **alkaloids** from aqueous solution of their salts, the precipitate being the free alkaloid. In some cases the precipitate is soluble in excess of the hydroxide. The precipitation is sometimes prevented by alcohol which is a solvent for the alkaloids. 11. They decompose some of the **alkaloids**, such as atropine, hyoscyamine, cocaine, and aconitine, when left in contact for some time, or more quickly when heated. 12. Alkali hydroxides decompose many of the **glucosides** when warmed with them. 13. They dissolve some principles, as **santonin** and **cantharidin**. 14. With **fats** and **fixed oils** they form glycerin and a salt (soap) of the fat acid. 15. With **resins** they form resin soaps. 16. They decompose some substances like **salol** and **oil of winter-green**. [See **POTASSIUM**.]

**Liquor Sodii Silicatis.**—1. This solution is precipitated by **alcohol**, concentrated mineral **acids**, or dilute acids with heat. 2. It gelatinizes mucilage of **acacia**. 3. It is strongly alkaline.

**Lithium.**—1. The soluble lithium salts are precipitated from their solutions by soluble **carbonates**, the precipitate being lithium carbonate. 2. Soluble **phosphates** precipitate lithium phosphate. 3. With the exception of the carbonate and phosphate, the common lithium salts are generally soluble in water and in alcohol.

**Magnesii Oxidum.**—1. Magnesia combines with **acids** to form salts. 2. With fifteen times its weight of **water** it soon forms a gelatinous mass, due to the formation of magnesium hydroxide. Magnesium hydroxide is slightly soluble in water, and its action is similar to that of the fixed alkalies but weaker. 3. With sixteen times its weight of **copaiba** magnesia makes a thick or solid mass on standing, the copaiba combining to form magnesium copaivate. 4. Magnesia absorbs water and **carbon dioxide** from the air. [See MAGNESIUM and LIQUOR POTASSII HYDROXIDI.]

**Magnesium.**—Soluble salts of magnesium in concentrated aqueous solution are precipitated: 1. by the **fixed alkali hydroxides** and the **hydroxides of barium, strontium, calcium**, as magnesium hydroxide; 2. by the normal **carbonates** of the fixed alkali metals, as basic carbonate of magnesium; 3. by the alkaline **phosphates**, as magnesium phosphate; 4. by alkaline **arsenates**, as magnesium arsenate; 5 by soluble **sulphites, oxalates, or tartrates**, as magnesium sulphite, oxalate, or tartrate respectively. 6. **Ammonium hydroxide or carbonate** scarcely precipitates magnesium salts, and may prevent to some extent the precipitation by the fixed alkali hydroxides and carbonates.

**Manganum.**—1. Salts of manganese in aqueous solution are precipitated by the fixed **alkali hydroxides** as manganous hydroxide, white but soon turning brown in the air from oxidation. **Ammonium hydroxide** in the presence of ammonium salts scarcely precipitates manganous salts. 2. The **alkali carbonates, phosphates, or cyanides** precipitate the manganous carbonate, phosphate, or cyanide, all of which are white when first precipitated, but darken on exposure to air. 3. Manganous salts in alkaline mixture are oxidized to manganese dioxide by **chlorine, bromine, iodine, and hydrogen dioxide**.

**Mel.**—1. The presence of honey prevents the precipitation of some of the metallic salts by the alkali hydroxides. 2. Honey decomposes **borax**, with liberation of boric acid, the reaction being somewhat similar to that between glycerin and

borax. [See GLYCERINUM, No. 1.] 3. Honey when triturated with strong oxidizing agents, such as **potassium chlorate** or **potassium permanganate**, is liable to form an explosive mixture. 4. Water, added to resinous tinctures, precipitates the resin which adheres to the bottle; honey prevents to a considerable extent the formation of sticky masses and helps to keep the resin suspended.

**Menthol.**—1. Menthol when triturated dry gives a liquid or soft mass with many solids. [See page 267.] 2. Fuming **nitric acid** forms an explosive oil (M. & M., III. 203). 3. **Potassium permanganate** in solution decomposes menthol, forming pimelic, formic, propionic, butyric, and oxymenthyllic acids (M. & M., III. 203). 4. Adding water to an alcoholic solution of menthol causes separation of the menthol as an oily liquid. 5. Many concentrated **acids** or concentrated solutions of sodium salicylate, dissolve menthol, the addition of water precipitating it again.

**Methylis Salicylas.**—1. Methyl salicylate, or artificial oil of wintergreen, gives with a dilute solution of a **ferric salt** a deep violet color, due to the formation of ferric salicylate. 2. **Alkali hydroxides** decompose it, forming methyl alcohol and a salicylate. 3. Methyl salicylate has incompatibilities quite similar to those of the soluble salicylates. [See ACIDUM SALICYLICUM.]

**Methylthioninæ Hydrochloridum.**—1. Methylene blue is decomposed by a strong solution of **potassium** or **sodium hydroxide** liberating the base as a violet precipitate (M. R., IV. 359). Sodium hydroxide gives a purplish color and in excess a violet color (N. S. D., 971). 2. **Reducing agents** cause the formation of a colorless substance, which again takes up oxygen, forming methylene-blue (M. R., IV. 359). 3. **Sulphuric acid** changes the blue aqueous solution to a bright green color (M. R., IV. 359). 4. In aqueous solutions **potassium iodide** and **potassium bichromate** precipitate the base as an iodide and a chromate (Allen, III. Part 1, 353).

**Morphina.**—1. Morphine combines with **acids** to form

salts. 2. Morphine is precipitated from solutions (not too dilute) of its salts by **ammonium, potassium, sodium, calcium, and barium hydroxides** by **carbonates** of the alkalies, and by **borax**. The precipitate is soluble in a large excess of the above-mentioned fixed hydroxides, but not so readily in the carbonates. Morphine tartrate is not precipitated by fixed or volatile hydroxides (Blyth, 292). 3. The **bicarbonates** of the alkalies precipitate only a portion of the morphine from neutral solutions of its salts; tartaric acid prevents the precipitation (Watts, III. 1053). 4. Morphine is precipitated from solutions of its salts by **lead subacetate** (not neutral lead acetate), by **potassium chromate**, and by the **general alkaloidal reagents**. 5. **Potassium cyanide** precipitates morphine usually as the free alkaloid, due to the alkalinity of the potassium salt, although some say that morphine cyanide is precipitated. 6. **Silver nitrate** is reduced by morphine and gives a red coloration (Sohn, 67). 7. **Ferric chloride** in nearly neutral solution gives a blue coloration, changing to a dirty green. This coloration is prevented or destroyed by excess of acid or alcohol. 8. **Nitric acid** gives a red color, changing to an orange and then a light yellow. 9. **Iodates** are reduced, liberating iodine. 10. **Gold chloride** precipitates morphine; the precipitate is first yellow, then blue, and finally purple. The gold is reduced. 11. **Nitrous acid** or **spirit of nitrous ether** produces a yellow color with morphine. Morphine is converted into nitroso-morphine, pseudomorphine, and a base  $C_{17}H_{21}NO_5$  (M. & M., III. 436). 12. With **chlorine** a solution of morphine gives a yellow to an orange color, and if ammonia is added it is changed to red brown. 13. **Chlorates** oxidize morphine. 14. Morphine is oxidized by an alkaline solution of **potassium permanganate**, forming an acid (M. & M., III. 436). With an acid solution of potassium permanganate a green coloration is produced. 15. **Iodine** unites with morphine to form iodomorphine (Watts, III. 1052). 16. In a moderately strong aqueous solution morphine is precipitated as the free alkaloid by codeine. [See ALKALOIDS.]

**Naphthalenum.**—1. Naphthalene is converted into nitro- or dinitro-naphthalene by **nitric acid**, according to the strength of the acid used (Allen, II. 199). 2. **Chlorine** and **bromine** form chloro- and bromo-derivatives. 3. Triturated dry with **phenol** or **salol** naphthalene produces a liquid. It gives a damp powder with **pyrocatechin**.

**Olea Fixa.**—1. Fixed oils with solutions of **alkali hydroxides**, **lime water**, and **oxides** of many metals, form oleates (soaps) of the base and glycerin. 2. The olein of some fixed oils with **nitric acid** or **nitrous acid gas** forms the isomeric elaidin, which is solid. 3. Fixed oils absorb and combine with **bromine** and **iodine**, forming addition products. 4. Concentrated **nitric acid** and concentrated **sulphuric acid** give various color reactions with different oils. 5. Fixed oils do not dissolve readily in alcohol, except castor and croton, or in glycerin.

**Olea Volatilia.**—1. Volatile oils with concentrated **sulphuric acid** generally give a yellow color, turning brown and sometimes red. 2. Concentrated **nitric acid** gives color-reactions with many oils. 3. **Potassium hydroxide** saponifies the resinified portions of the oils. 4. **Ferric chloride** gives colors with some of the oils. [See FERRICUM, Nos. 28, 29, 30, and 31.] 5. **Iodine** reacts violently with some oils, particularly the hydrocarbon oils. 6. In aqueous solution the addition of very soluble salts sometimes throws the oil out of solution.

**Oleum Æthereum.**—1. Ethereal oil with **water** is slowly decomposed, becoming acid (N. S. D., 1054). 2. The sulphuric acid is not precipitated by the general precipitants of this acid because it exists in the form of sulphovates, which are soluble.

**Oleum Amygdalæ Amaræ.**—1. Oil of bitter almonds contains chiefly benzaldehyde with a little hydrocyanic acid; the artificial oil consists of benzaldehyde. 2. Benzaldehyde is readily oxidized by the **air** and by **oxidizing agents**, forming benzoic acid, which may crystallize so as to form a mass. Alcohol prevents this to some extent. 3. With an aqueous or alcoholic solution of **potassium hydroxide** it gives

benzyl alcohol and potassium benzoate. 4. **Ammonia water** converts it into crystalline hydrobenzamid, which is again resolved by acids into ammonia and benzoic aldehyde. A mixture of ammonia and the oil turns yellow on standing. 5. **Chlorine** converts it into benzoyl chloride. 6. Benzaldehyde with **resorcin** in the presence of hydrochloric acid forms a resin; **phenol** and **pyrocatechin** act similarly (M. & M., I. 472). 7. With an aqueous solution of **sodium bisulphite** a crystalline compound is produced.

**Oleum Caryophylli.**—1. Oil of cloves dissolved in a little alcohol gives a bright green color when a solution of **ferric chloride** is added. If the solution of ferric chloride is quite dilute, a blue color is produced, which soon changes to yellow (U. S. P., 310). Clove water gives a yellow or brown solution or precipitate with a solution of ferric chloride. 2. **Iodine** dissolves quietly in the oil. 3. **Nitric acid** changes its color to a deep red, and if heat be used the oil is converted into oxalic acid (U. S. D., 840). 4. Strong solutions of **alkalies** dissolve it (N. S. D., 1066).

**Oleum Cinnamomi.**—1. Oil of cinnamon dissolved in alcohol gives a brown color with a solution of **ferric chloride**. Cinnamon water with solution of ferric chloride gives a brown color and a slight precipitate. 2. With a saturated solution of **sodium bisulphite** the oil solidifies to a crystalline mass. 3. **Nitric acid** slowly oxidizes it to a crystalline mass of cinnamic acid. 4. Cinnamon water gives a turbidity with a solution of **lead acetate**.

**Oleum Lini.**—1. Linseed oil is ignited by fuming **nitric acid**. Nitric acid of sp. gr. 1.33 turns it green and afterwards brown. 2. **Alkali hydroxides** convert it into a soft soap. 3. An alkaline solution of **potassium permanganate** converts it into sativic acid (M. & M., III. 147). 4. Exposed to **air** the oil oxidizes and ultimately becomes solid. If the oil be distributed through cotton, the heat generated by the oxidation may be sufficient to cause ignition. 5. **Iodine** and **bromine** form additive compounds.

**Oleum Terebinthinae.**—1. Oil of turpentine with a small proportion of **sulphuric acid** is partially converted into terebene. 2. Dry **hydrochloric acid gas** with oil of turpentine forms a crystalline monohydrochloride of terpene. This has been called “artificial camphor.” 3. **Chlorine** and **bromine** react so violently that the oil is frequently ignited. 4. **Iodine** is dissolved by oil of turpentine to form a green solution, which afterwards becomes hot and gives off vapors of iodine and hydriodic acid; and when considerable quantities of iodine and turpentine oil are brought suddenly together, explosion frequently ensues. 5. Heated with **chlorinated lime**, oil of turpentine yields chloroform. 6. If oil of turpentine is left in contact with **water**, it gradually changes into terpin hydrate. This reaction is hastened by the presence of nitric acid, or by alcohol (U. S. D., 878). 7. **Nitric acid** converts the oil into resinous matter, the violence of the reaction and the products formed depending on the strength of the acid. Some of the products formed are acetic, propionic, butyric, paratoluic, and terebic acids. 8. The oil when exposed to **air** slowly absorbs oxygen and forms a resinous substance, which is broken up into hydrogen dioxide and camphoric acid (U. S. D., 879). Oil of turpentine absorbs **oxygen** and gives formic and acetic acids, carbon dioxide, ozone, and resinous bodies (Watts, v. 921).

**Oleum Theobromatis.**—1. Cacao butter is softened by rubbing with one half its weight of **chloral hydrate**, **camphor**, **euphorin**, **menthol**, **naphthalene**, **thymol**, or **salol**. The mixture can be hardened by allowing it to stand or by adding some melted spermacetti.

**Opium.**—1. A solution of opium contains many alkaloids and other substances that are generally incompatible with the inorganic **salts**, **general alkaloidal reagents**, and many other compounds. 2. Tincture of opium gives a violet-red color with tincture of iron. [See MORPHINA, ALKALOIDS, and ACIDUM MECONICUM.]

**Orthoform, New.**—1. An aqueous solution of orthoform

gives a violet to brown-black color with tincture of **ferrie chloride**. 2. It reduces solutions of **silver nitrate** and **potassium permanganate**. 3. With a strong solution of **mercuric chloride** it gives a yellow flocculent precipitate.

**Oxidizing Agents.**—Strong oxidizing agents, such as chromic, nitric, and nitrohydrochloric acids, chromates, nitrates, chlorates, permanganates, should not be triturated with substances that are easily oxidized, as, for instance, **sulphur**, **sulphides**, **sulphites**, **hypophosphites**, **iodine**, **charcoal**, **tannic acid**, **carbolic acid**, **honey**, **sugar**, **glycerin**, **starch**, and **vegetable matter**.

**Pancreatinum.**—1. An aqueous solution of pancreatin is precipitated by strong **alcohol**. 2. An aqueous solution is precipitated by **heat**, **mineral acids**, **metallic salts**, **absolute glycerin**, strong **alcohol**, and **tannic acid** (N. S. D., 1136). 3. The activity is lessened by long exposure to **acids** or **air**.

**Paraldehydum.**—1. Paraldehyde with fixed **alkali hydroxides** forms aldehyde resin which resembles colophony. 2. It is a strong reducing agent and is oxidized to an acid. 3. **Chlorine** forms substitution products. 4. **Hydrocyanic acid** combines with aldehydes to form nitrites (M. & M., 1. 107). 4. Paraldehyde liberates iodine from **iodides** (Ph. Era, xvii. 298).

**Pelletierinæ Tannas.**—1. Pelletierine tannate in aqueous solution is precipitated by the **alkali hydroxides**, the precipitate being soluble in an excess of the fixed alkalies. 2. It is precipitated by solutions of the soluble salts of **lead**, **mercury** and **zinc**. 3. It reduces salts of **gold** and **silver**. 4. **Ferric chloride** gives a blue-black color.

**Pepsinum.**—1. Pepsin is rendered inert by **alkaline substances**, or heavy **metals**, by prolonged contact with **alcohol**, or by **tannic acid**. 2. Hydrochloric acid stronger than 0.5 per cent. inhibits and destroys its activity.

**Phenacetinum** (*acetphenetidin*).—1. Phenacetin in strong aqueous solution gives with **chromic acid**, **chlorine**, **chlorinated lime**, **iodine**, and some other **oxidizing agents**, color-

tions varying from pink to red. These colorations are due to the presence of parphenetidin in the phenacetin, or upon its formation by decomposition of the phenacetin (M. R., iv. 359). 2. Heating phenacetin with hydrochloric acid and then adding a solution of **ferric chloride** gives a red color. 3. **Salicylic acid** when triturated with phenacetin is said to give a pasty mass. The writer failed to get anything but a dry powder. 4. Phenacetin triturated with **carbolic acid**, **chloral hydrate**, or **pyrocatechin** gives a liquid. 5. It is decomposed by strong **acids** or **alkalies**. 6. Phenacetin combines with **iodine** to form a compound known as iodophenin. 7. Phenacetin conceals the fluorescence of **quinine sulphate**, especially in dilute solutions. 8. **Spirit of nitrous ether** slowly gives a yellow color, becoming more of a red brown.

**Phenocoll Hydrochloridum.**—1. Phenocoll hydrochloride in aqueous solution is precipitated by the **alkaline hydroxides** and **carbonates** as the free base. 2. **Piperazine** is alkaline and precipitates the phenocoll. 3. Phenocoll acts like an alkaloid and is precipitated from aqueous solution of its salts by many of the agents that precipitate alkaloids. 4. It destroys the fluorescence of **quinine sulphate**. 5. Tincture of **ferric chloride** gives a deep red solution which turns brown green. 6. **Gold** and **silver** salts and **potassium permanganate** are reduced. 7. Tincture of **iodine** gives a brown precipitate which redissolves in excess of phenocoll, and the iodine is decolorized.

**Phenocoll Salicylas, Salocoll.**—1. Salocoll gives a violet color with tincture of **ferric chloride**. 2. It destroys the fluorescence of **quinine sulphate**. 3. With **spirit of nitrous ether** it gives a yellow color. 4. It liquefies when triturated with **chloral hydrate**.

**Phenol.**—1. Carbolic acid exposed to the **air** absorbs enough moisture to liquefy it. It becomes pink, red or brown. The coloration is said to be due to ammonia and ammonium nitrite in the air, to the iron in the tin-can container, to the alkali in the glass bottle, to impurities in the phenol, to hydrogen di-

oxide acting on a metal in the presence of ammonia or to oxidation of phenol itself. The addition of 5 cc. of a 10 per cent. solution of sulphurous acid to 20 K. of carbolic acid is said to prevent coloration. 2. Carbolic acid with **ammonia water** gives a colorless solution which slowly becomes green, then deep blue, and finally purplish blue. 3. With **ammonia water** and a solution of **chlorinated soda** it gives a deep blue. 4. Carbolic acid combines with concentrated solutions of **fixed alkali hydrates** to form carbolates. It does not combine with alkali carbonates, except perhaps on boiling. 5. Alkaline solutions of carbolic acid absorb atmospheric **oxygen**, forming dark-colored products. 6. Carbolic acid with the U. S. P. solution of **ferric chloride** gives no change in color, but on adding water a green is produced and on further dilution gives a violet-blue color. This violet-blue color is prevented or destroyed by most mineral and organic acids, by some salts, and by many organic substances such as alcohol, ether, and glycerin. 7. Adding phenol to a solution of lead **subacetate** (not lead acetate) or to the dilute solution of lead subacetate gives a sticky precipitate, which is soluble in alcohol. Glycerin tends to prevent it; a ten per cent. solution of phenol in glycerin gives no precipitate at once with solution of lead subacetate, but a twenty per cent. solution does. 8. **Hydrogen dioxide** oxidizes it to pyrocatechin, quinone, and hydroquinone (M. & M., III. 832). The solution slowly becomes yellow to red brown on standing. 9. **Potassium permanganate** oxidizes it to oxalic acid and carbon dioxide (N. S. D., 1160). 10. **Nitric acid** oxidizes it to mono-, di-, and tri-nitrophenol, the latter being picric acid. 11. **Nitrous acid** forms nitroso-phenol. **Spirit of nitrous ether** with carbolic acid gives a yellow color, changing to a red brown in a few minutes, then to a deep brown-red; after some hours a precipitate forms. 12. Carbolic acid with strong **sulphuric acid** forms phenolsulphonic acid. 13. Phenol is scarcely, if at all, attacked by **iodine** (Watts, IV. 390). Pouring a mixture of equal parts of tincture of iodine and phenol into boiling water gives a colorless solution. 14. An aqueous solution of phenol with **bromine water**

gives a crystalline precipitate of tribromo-phenol which is not so very soluble in dilute alcohol. 15. Carbolic acid reduces salts of several of the **metals**, as **silver**, **copper**, and **mercury**. 16. **Gelatin** is completely dissolved by strong carbolic acid but is coagulated when the acid is added in excess to its aqueous solution (Allen, II. 539). 17. Carbolic acid coagulates aqueous solutions of **albumin**. 18. It coagulates **collodion**, separating the nitro-cellulose as a gelatinous mass. 19. Pure **alcohol**, and to a less extent pure **glycerin**, neutralizes the caustic and poisonous effects of phenol. 20. Carbolic acid softens **oil of theobroma** when rubbed with it. 21. On mixing aqueous solutions of carbolic acid and **antipyrine** an oily liquid settles to the bottom. 22. Crystalline carbolic acid gives a soft mass or a liquid when triturated with **agurin**, **alumnol**, **chloralamid**, **quinine sulphate**, **terpin hydrate**, and a large number of other chemicals. [See page 267.] These reactions are due in some cases to the formation of new chemical compounds, and in some cases probably to the fact that carbolic acid is hygroscopic, and also that it liquefies when warmed by trituration.

**Phenylis Salicylas.**—1. Salol in alcoholic solution gives a violet color when a dilute solution of **ferric chloride** is added to it. In aqueous solution no increase of color results. 2. **Bromine water** added to an alcoholic solution of salol will cause the formation of long needle-shaped crystals, consisting of a bromo-derivative. 3. Strong solution of **alkalies** heated with salol saponify it, forming a salicylate and carbolic acid (Allen, III. part I. 60). 4. When salol is triturated dry with many solids a mass or liquid results. [See page 267.]

**Phosphorus.**—1. Phosphorus is oxidized in the **air** forming oxides of phosphorus, and may cause fire. 2. A warm solution of **potassium** or **sodium hydroxide** or **lime water** with phosphorus gives a hypophosphite and phosphorus hydride gas. 3. In the presence of water, **chlorine**, **bromine**, or **iodine** oxidizes phosphorus and forms phosphoric acid, and hydrochloric, hydrobromic, or hydriodic acid. 4. Phosphorus is oxidized by **nitric acid**, **chromic acid**, old oil of turpen-

tine, and other substances rich in oxygen. 5. When phosphorus is triturated with **potassium chlorate**, **chromic oxide**, **lead dioxide**, **mercuric oxide**, **silver oxide**, **potassium bichromate**, **potassium nitrate**, **sulphur**, or **sulphides**, explosion is liable to take place.

**Physostigmina.**—1. Physostigmine is precipitated from aqueous solutions of its salts by the **general alkaloidal reagents**, except picric acid and platinum chloride. 2. Alkalies give a white precipitate which immediately turns pink and dissolves in excess of the alkali, forming a pink or red solution which fades to a yellow green (N. S. D., 1172). 3. Aqueous solutions of its salts soon turn red. A drop of a ten per cent. solution of hypophosphorus acid is said to prevent the change. The red color is due to the formation of rubreserine (N. S. D., 1170). 4. **Gold chloride** gives a blue to a violet coloration. 5. A solution of **chlorine** or **bromine** gives a red coloration. 6. **Nitric acid** gives a yellowish-red color.

**Picrotoxinum.**—1. Picrotoxin is soluble in solutions of acids and alkalies without combining with them (N. S. D., 1175).

**Pilocarpinæ Hydrochloridum.**—1. Pilocarpine hydrochloride in aqueous solution is precipitated by the reagents that generally precipitate alkaloids, except that it is not readily precipitated by alkali hydroxides and carbonates. 2. When this alkaloidal salt is mixed with **calomel** in the presence of moisture a darkening occurs. This is probably due to the separation of metallic mercury while at the same time some mercuric chloride is formed which combines with the alkaloid. Pilocarpine nitrate gives no black color (U. S. P., 343). 3. **Potassium permanganate** oxidizes it to pyridin (M. & M., iv. 275).

**Piperazina.**—1. Piperazine is strongly alkaline and combines with **acids** to form salts. 2. With an aqueous solution of piperazine **alum** gives a white precipitate. 3. **Ferrous sulphate** gives a dark green precipitate which turns brown on standing. 4. **Ferric chloride** gives a red-brown precipitate. 5. An aqueous solution of piperazine precipitates solutions of **mercuric chloride**, **copper sulphate**, **lead acetate**, **zinc**

sulphate, potassium mercuric iodide, Donovan's solution, tincture of iodine, and picric acid. 6. On account of its strong alkalinity piperazine gives precipitates with solutions of alkaloidal salts and with some inorganic salts. 7. Potassium permanganate and silver nitrate are reduced by piperazine. 8. Sodium hypochlorite solution forms a body with piperazine that explodes when heated to a temperature of  $80^{\circ}$ – $85^{\circ}$  C. (M. & M., iv. 349). 9. Bromine water forms dibromo-piperazine (M. & M., iv. 349). It decolorizes bromine water without giving a precipitate. 10. With spirit of nitrous ether piperazine gives a yellow to a red solution. 11. Quinine is said to give an amorphous violet-brown body with piperazine (M. & M., iv. 349). Piperazine gives a white precipitate with a solution of quinine sulphate and destroys the fluorescence. 12. Phenol combines with piperazine. 13. A solution with tannic acid gives a green color. 14. When piperazine is triturated dry with butyl chloral hydrate, acetanilide, antipyrine, carbolic acid, chloral hydrate, or phenacetin, a liquid or soft mass is formed. This is due in some instances to chemical combination and sometimes to the fact that piperazine is very hygroscopic.

**Plumbi Acetas.**—1. Lead acetate in aqueous solution is precipitated by the fixed alkali hydroxides as lead hydroxide which is soluble in excess of the alkali hydroxide. The precipitation is prevented by the presence of glycerin and sugar to some extent. 2. Ammonium hydroxide does not precipitate lead acetate, except from a concentrated solution. 3. The soluble carbonates precipitate the white basic carbonate of lead. 4. Borax precipitates the white lead borate. Precipitation is prevented to some extent by glycerin and sugar. 5. Sulphuric acid and the soluble sulphates precipitate the white lead sulphate. 6. Hydrochloric acid and the soluble chlorides precipitate from not too dilute solutions of lead acetate the white lead chloride. 7. The soluble bromides precipitate the white lead bromide. 8. The soluble iodides precipitate the yellow lead iodide. 9. Soluble chromates

precipitate the yellow lead chromate. 10. **Sodium phosphate** precipitates the white lead phosphate. 11. **Alkali sulphites** precipitate the white lead sulphite. 12. The soluble **cyanides** precipitate white lead cyanide. 13. **Tannic acid** and solutions containing it precipitate the yellow-gray lead tannate. 14. Solutions of lead acetate are precipitated by neutral soluble **benzoates, citrates, tartrates, and salicylates**. 15. **Pyrogallol** gives a white precipitate which becomes brown and black on exposure to air and light. 16. Lead acetate gives a precipitate with some **coloring matters, gums, resins, neutral principles, glucosides, and alkaloids**. 17. With a solution of **opium** lead acetate forms the acetates of the alkaloids and the insoluble lead meconate and sulphate. 18. Lead acetate gives a liquid or soft mass when rubbed with **alum, zinc sulphate**, and other solids. [See page 267.]

**Potassii Bitartras.**—1. Cream of tartar combines with the **hydroxides** and **carbonates** of the **alkalies** to form neutral soluble salts. 2. Cream of tartar becomes more soluble in solutions of **borax** or **boric acid**. 3. It is acid in reaction, and has the incompatibilities of tartaric acid. [See ACIDUM TARTARICUM.]

**Potassii Permanganas.**—1. Potassium permanganate in acid solution is reduced to the manganous condition by **nitrous acid** and **nitrites**, forming nitric acid; 2. by **hydrochloric acid** and **chlorides**, liberating chlorine; 3. by **hydrobromic acid** and **bromides**, liberating bromine; 4. by **hydriodic acid** and **iodides**, liberating iodine; 5. by **sulphites** and **hyposulphites**, forming sulphates; 6. by **mercurous compounds**, forming mercuric compounds; 7. by **arsenites**, forming arsenates; 8. by **ferrous compounds**, forming ferric compounds; 9. by **hypophosphites**, forming phosphates; 10. by **ammonia**, forming nitrates. 11. With **hydrogen dioxide water** mixed with sulphuric acid, potassium permanganate forms manganous sulphate, potassium sulphate, water, and oxygen, the oxygen coming from both the permanganate and hydrogen dioxide. 12. **Tartaric acid** is converted into formic acid and carbon dioxide, more readily in a neutral or alkaline

mixture (M. & M., IV. 642). 13. **Carbolic acid** is oxidized by potassium permanganate, forming oxalic acid and carbon dioxide. 14. **Alcohol** is oxidized to aldehyde and acetic acid, the manganese dioxide and monoxide being precipitated. 15. **Glycerin** gives a precipitate similar to that produced by alcohol, and is oxidized to formic, propionic, and tartronic acids and carbon dioxide (M. & M., II. 618). 16. In dilute aqueous solution potassium permanganate is reduced by nearly all **organic matter**; in concentrated solution the reaction may be so great as to cause explosion. 17. When potassium permanganate is triturated dry with **sulphur, sulphides, reduced iron, hypophosphites, charcoal, sugar, glycerin, alcohol, tannic acid, oxalic acid, picric acid, fats, oils, gums,** and other **readily oxidizable matter**, an explosion is liable to ensue. 18. The permanganates are all soluble in water, except silver, which is sparingly soluble. They are insoluble in alcohol.

**Potassium.**—1. Potassium salts in the presence of a solution of **platinic chloride** and hydrochloric acid give a yellow precipitate of a double compound of platinum and potassium chloride. 2. Most neutral potassium salts in not too dilute aqueous solution with **sodium bitartrate** give a precipitate of potassium bitartrate. 3. A solution of the hydrate or carbonate of potassium with an excess of **tartaric acid** gives a precipitate of potassium bitartrate. [See LIQUOR POTASSII HYDROXIDI.]

**Protargol.**—1. Protargol is very slightly alkaline. It turns darker on exposure and should be protected from **light**. 2. An aqueous solution gives no precipitate with ammonia, but with considerable **potassium** or **sodium hydroxide** it gives a little precipitate, and the solution becomes darker. 3. Dilute **acids** give precipitates (said to be unchanged protargol) which dissolve on diluting with water or adding strong acids. 4. It gives precipitates with many of the astringent **metallic salts**, as silver nitrate, lead acetate, zinc sulphate, alum, ferric chloride,

and mercuric chloride. The cautious addition of dilute ammonia water sometimes partially dissolves the precipitates, but reprecipitation may follow. 5. Protargol reduces **potassium permanganate**. 6. It gives precipitates with solutions of many **alkaloidal salts**. It has been suggested to use a one and a half per cent. of boric acid solution as a solvent. This is not always sufficient and a saturated solution of boric acid works better, particularly with cocaine hydrochloride.

**Pyoktannin**.—1. Pyoktannin in solution is decomposed slowly in the **light**. 2. Fixed **alkali hydroxides** added to a solution of pyoktannin decolorize the solution and cause a deposit of a red precipitate. 3. **Ammonia** decolorizes a solution of pyoktannin and gives a purplish precipitate. 4. Pyoktannin is said to be incompatible with **mercuric chloride**.

**Pyramidon**, *Dimethylamido Antipyrine*.—1. A solution of pyramidon is colored a deep blue to a violet by **nitric acid**, **ferric chloride**, **silver nitrate**, or **hypochlorites**. 2. Tincture of **iodine** gives a violet liquid with a solution of pyramidon and an excess of iodine gives a brown precipitate. 3. A solution of **mercuric chloride** gives a white precipitate, and on standing the liquid becomes purplish. 4. **Calomel** is turned dark by a solution of pyramidon and the liquid slowly becomes purplish. 5. It reduces **potassium permanganate**. 6. **Tannic acid** gives a white precipitate. 7. It gives a white crystalline precipitate with a solution of **quinine bisulphate**. 8. It gives a white precipitate with **alum**. 9. It gives a mass when rubbed with **chloral hydrate** or **phenol**.

**Pyrocatechin**.—1. An alkaline solution of pyrocatechin assumes a green color, changing to brown, and finally black. 2. With a solution of **ferric chloride** it gives a green color, changed to a violet red by ammonia. 3. With a solution of **lead acetate** it gives a white precipitate. 4. **Nitric acid** acts violently, converting it into **oxalic acid** (M. & M., IV. 358). 5. **Ammonium carbonate** with water converts the pyrocatechin into pyrocatechuic acid (M. & M. IV. 358). 6. With a concentrated solution of **pyrocatechin lime water** gives a green-

ish color. 7. It reduces **silver nitrate** to metallic silver. 8. Pyrocatechin gives a mass or liquid when triturated with many solids. [See page 267.]

**Pyrogallol.**—1. Pyrogallic acid in aqueous solution gradually absorbs oxygen from the **air** and becomes brown red and acid. The coloration takes place more rapidly in the presence of alkalies, changing to nearly black. 2. With **ammonia** pyrogallein is formed (M. & M., IV. 359) and the solution becomes red. 3. With a solution of a **ferrous sulphate** pyrogallol gives a deep blue solution, changing to green and ultimately red. 4. With a solution of **ferric chloride** a red color is formed at once, and it is turned to violet by adding ammonia. 5. With a solution of **ferric acetate** a purple-black coloration is formed. 6. With **lead acetate** pyrogallol gives a white precipitate which turns dark on exposure. 7. With **lime water** a purple color is produced, rapidly changing to brown and black. 8. Pyrogallic acid is changed to purpurogallin by an alcoholic solution of **silver nitrate**, by an aqueous solution of **potassium permanganate**, or by an aqueous solution of **ferric chloride** in excess (M. & M., IV. 359). 9. Pyrogallol in aqueous solutions reduces salts of **silver**, **mercury**, and **gold**, and it is oxidized to acetic and oxalic acids (Richter, II. 164). 10. Pyrogallol gives a liquid or soft mass when rubbed with many solids. [See page 267.]

**Pyroxylinum.**—1. Soluble gun-cotton when damp undergoes decomposition, and may ignite or cause an explosion. 2. Treated with **alkalies** in concentrated solution it is decomposed, giving up its nitric acid. 3. The nitro-cellulose is converted back to cellulose by **reducing agents**, such as ferrous salts or alkali sulphides. [See COLLODIUM.]

**Quinina.**—1. Quinine unites with **acids** to form salts. 2. Quinine is precipitated from aqueous solutions of its salts by all the reagents mentioned under ALKALOIDS, Nos. 2 and 3, except bromides and iodides. 3. Concentrated solutions of quinine sulphate are precipitated by **potassium iodide**. In acid solutions it is slowly precipitated by the iodine liberated from the

iodide by the action of the acid and air. It is preferable to leave out the acid and use quinine bisulphate. 4. **Hypophosphorous acid** aids the solution of quinine sulphate, but if added in sufficient amount **potassium hypophosphite** destroys the fluorescence and causes precipitation. 5. Quinine is precipitated from solution of its salts by the **alkali acetates** as the voluminous quinine acetate. [See ACIDUM ACETICUM, No. 4.] 6. **Citric acid** aids the solution of quinine sulphate in water. Adding an **alkali citrate** destroys the fluorescence and precipitates the quinine. 7. Quinine is precipitated from its concentrated aqueous solutions by **benzoates**, **salicylates**, and **tartrates**, the precipitate generally being bulky. 8. Quinine gives a blue fluorescence with nearly all **acids** that contain oxygen. 9. The fluorescence is destroyed by the **halogen acids**, **salts** of the **halogens**, **resorcin**, **antipyrine**, **acetanilide**, **phenacetin**, **phenocoll hydrochloride**, or **piperazine**. 10. When the alkaloid quinine is heated with solutions of **ammoniacal salts** ammonia gas is liberated. 11. Quinine sulphate is oxidized by **potassium permanganate** to pyridin tricarboxylic acid, oxalic acid, and ammonia (M. & M., iv. 375). 12. With **resorcin** a solution of quinine sulphate or bisulphate a precipitate is formed. 13. Quinine bisulphate in **sunlight** turns yellow and then brown-red. 14. When quinine sulphate is rubbed with **phenol** or **thymol** it gives a soft mass; with **chloral hydrate** it gives a damp powder or stiff mass. 15. The solubility of quinine sulphate in water is increased by the presence of certain compounds, as **ammonium chloride**, **potassium nitrate**, and **antipyrine**. [See ALKALOIDS.]

**Resina.**—1. Pine resin when triturated with **menthol**, **salol**, **carbolic acid**, or **urethane** makes a liquid or sticky mass. 2. **Nitric acid** oxidizes it to isophthalic and trimellitic acids (M. & M., I. 1). 3. **Potassium permanganate** oxidizes it to formic, acetic, and carbonic acids (M. & M., I. 1).

**Resinæ.**—1. With aqueous solutions of **alkali hydroxides** or **carbonates** resins form resin soaps which are generally soluble in water. 2. **Nitric acid** converts them into artificial

tannin (U. S. D., 1150). 3. Concentrated **sulphuric acid** dissolves many of the resins with decomposition and gives color reactions with some. 4. Tincture of **ferric chloride** gives different colors with resinous substances. [See FERRICUM, No. 26.] 5. **Alcohol** containing **hydrochloric acid** is colored red to violet by myrrh; yellowish brown to green by guaiac; yellow, changing through brown to cherry-red, by benzoin or balsam of Tolu; greenish, changing to dingy violet, by asafœtida; and brown by some other resins. 6. Alcoholic solutions of resins, as tincture of myrrh or benzoin when mixed with water give precipitates that generally adhere to the bottle or agglutinate, particularly if there is a metallic salt dissolved in the water. Honey helps to suspend the resin and keep it from sticking. About one dram of honey to seven drams of the aqueous solution makes a presentable mixture.

**Resorcinol.**—1. An aqueous solution exposed to the air becomes red and brown. This reaction is hastened by the presence of **alkalies**. 2. With a dilute solution of **ferric chloride** resorcin gives a violet coloration. 3. With **chlorinated lime** or **soda** a solution of resorcin gives a violet coloration changing to yellow. 4. **Nitrous acid** or **spirit of nitrous ether** gives a dark red solution with resorcin. 5. A solution of quinine sulphate or bisulphate is precipitated by it and the fluorescence is destroyed. 6. Resorcin produces a liquid or soft mass when triturated with many solids. [See page 267.]

**Saccharum.**—1. A solution of sugar heated with **lime**, **magnesia**, **litharge**, and other metallic **oxides** and **hydroxides** form saccharates, chemical compounds which are more or less soluble in water. 2. The presence of sugar hinders or prevents the precipitation, or dissolves the precipitate, of many metallic hydroxides or oxides which are normally formed when alkali hydroxides are added to solutions of metallic salts. The interference is most marked, in case of **lead**, **antimony**, **copper**, **mercuric**, **ferrous**, **ferric**, **aluminum**, **zinc**, **calcium**, and **magnesium salts**. 3. Very strong **nitric acid** with sugar, in the cold, forms explosive nitrosaccharose (Allen, 1. 270).

Moderately concentrated nitric acid converts sugar into saccharic and tartaric acids, and with heat into oxalic acid and carbon dioxide (Allen, I. 270). 4. With concentrated **sulphuric acid** sugar is decomposed, forming carbon, while formic acid, sulphur dioxide, and other gases are given off (Allen, I. 271). 5. Sugar warmed with dilute solution of **acids**, or heated for some time with **water** is changed to invert-sugar. 6. When a concentrated solution of sugar and **potassium hydroxide** is heated, carbon dioxide, acetone, acetic, propionic, and oxalic acids are formed (M. & M., IV. 551). 7. Sugar combines with sodium chloride, forming deliquescent crystals (N. S. D., 1340). 8. **Chlorine** or **bromine** oxidizes sugar to gluconic acid, glucose and other products. The same reaction takes place in the presence of lead or silver oxide (M. & M., IV. 551). 9. **Iodine** with potassium carbonate and sugar yields a little iodoform (M. & M., IV. 551). Iodine is converted into hydriodic acid by heating with a solution of sugar (N. S. D., 1340). 10. Dilute **chromic acid** solution oxidizes sugar to oxalic, formic, and carbonic acids (M. & M., IV. 551). 11. **Potassium permanganate** converts sugar into oxalic, formic, and carbonic acids (M. & M., IV. 551). 12. Sugar triturated with **potassium chlorate**, **permanganate**, or **bichromate**, or with other strong oxidizing agents, is liable to cause an explosion. 13. Syrup of hydriodic acid or ferrous iodide sometimes slowly turns brown, due to the action of the acid or iodide on the sugar. 14. Exposed to the **light** it slowly changes into glucose (N. S. D., 1075). 15. Sugar renders the **fixed** and **volatile oils** to a certain extent miscible with water and forms with them an imperfect combination (N. S. D., 1074).

**Saccharum Lactis.**—1. Milk-sugar in alkaline solution reduces salts of **copper**. 2. **Nitric acid** first inverts milk-sugar and then forms mucic and saccharic acids, and if heated forms tartaric and racemic acids and finally oxalic acid. 3. Dilute **acids** invert milk-sugar, forming dextrose and galactose. 4. A mixture of sulphuric and nitric acids with milk-sugar gives lactose pentanitrate, which is explosive (M. & M., IV. 553).

5. **Chromic acid** with milk-sugar yields aldehyde (M. & M., iv. 553). 6. **Alkali permanganates** oxidize milk-sugar. 7. **Silver oxide** oxidizes it, forming oxalic, glycollic, and lactonic acids (M. & M., iv. 553). 8. Milk-sugar with a solution of **iodine** and sodium bicarbonate yields a little iodoform (M. & M., iv. 553). 9. Triturated with **oxidizing agents**, it is liable to cause an explosion.

**Salacetol.**—1. Salicyl-acetol is decomposed by **alkali hydroxides**, forming a salicylate.

**Salicinum.**—1. Salicin is not readily precipitated by any of the common precipitants. 2. Dilute **acids** and **water** with heat change it to glucose and saligenin.

**Salophen.**—1. Salophen dissolves in solutions of **potassium** or **sodium hydroxide** but is decomposed by them. Boiling the sodium hydroxide solution a blue color is developed, beginning at the top (N. S. D., 1165). 2. Tincture of ferric chloride gives a brown-red to violet color.

**Saloquinine.**—1. **Acids** dissolve it. 2. From the acid solutions, **alkali hydroxides** and **carbonates** and the general alkaloidal reagents precipitate it. 3. With a very dilute solution of **ferric chloride**, its alcoholic solution gives a reddish violet color.

**Santonin.**—1. Santonin on exposure to light turns yellow, forming photo-santoninic acid and a yellow-resinous body (A. D., 1718). 2. With **alkali hydroxides** in solution it forms santoninates, which are soluble in water. 3. An aqueous solution of santoninate is precipitated by **lead acetate** or **lead subacetate** as lead santoninate. It is also precipitated by **tannic acid**, **ferrous sulphate**, **copper sulphate**, **chlorine water**, and by **acids** if the solution of santoninate is not too dilute. 4. Santonin is turned pink or red by **potassium hydroxides** in the presence of alcohol. 5. Heated with **nitric acid**, santonin forms carbon dioxide, succinic, oxalic, and acetic acids (M. & M., iv. 429).

**Sapo.**—1. Aqueous solutions of soap are decomposed by **mineral acids**, which combine with the base, liberating the

free fat acid. 2. Aqueous solutions of **metallic salts** give precipitates of metallic oleates with soaps. 3. Soap is frequently alkaline, and when so it makes a black mixture with **calomel**, due to the mercurous oxide formed. 4. It may precipitate hydroxides or oxides from solutions of metallic salts.

**Sodii Thiosulphas.**—1. Sodium thiosulphate (hyposulphite) in aqueous solution is decomposed by nearly all **acids**, forming sulphur, and sulphurous acid. An aqueous solution of the salt slowly forms sulphur and a sulphite. 2. Aqueous solutions of thiosulphates are decomposed into hydrogen sulphide and sulphuric acid when boiled (M. & M., iv. 705). 3. Sodium thiosulphate precipitates, as thiosulphates, solutions of **barium chloride**, **silver nitrate**, **lead acetate**, and **mercurous nitrate**. The precipitates are white, but those of the last three salts turn black on standing, forming the sulphide of the metal and sulphuric acid. 4. Sodium thiosulphate with a solution of **ferric chloride** gives a dark violet color, due to ferric thiosulphate. The solution soon loses its color because the salt formed changes to ferrous sulphate. 5. In acid solution sodium hyposulphite reduces **iodine** to hydriodic acid; 6. **chlorates** to chlorine and hydrochloric acid; 7. **chromates** to chromic salts; 8. **permanganates** to manganic salts; 9. **arsenic** compounds to arsenous. 10. Sodium thiosulphate forms soluble double thiosulphates with many **metallic salts**. 11. Solutions of sodium thiosulphate dissolve **silver iodide**, **silver bromide**, **silver chloride**, **mercuric iodide**, **lead sulphate**, **lead iodide**, and other salts (Watts, v. 630). 12. With **calomel** in the presence of moisture it gives a black mixture. 13. In very dilute solutions it prevents the precipitation of some of the alkaloids by **gold chloride**. It combines with the gold to form a double thiosulphate. 14. An acidulated solution bleaches **vegetable colors** on account of its reducing properties. 15. When sodium thiosulphate is triturated with **potassium chlorate**, **nitrate**, or **permanganate**, or other strong **oxidizing agents**, explosion is liable to take place.

16. **Alcohol** precipitates sodium thiosulphate from an aqueous solution as an oily liquid (N. S. D., 1423). 17. Thiosulphates are generally soluble except lead, silver, mercurous and lead.

**Sozoiodol**, *Diiodopara phenolsulphonic Acid*.—1. An aqueous solution of sozoiodol gives a precipitate with **silver nitrate** and **lead acetate**. 2. It gives a violet color with a solution of **ferric chloride**. 3. It precipitates many of the **alkaloidal salts** from aqueous solution. 4. **Oxidizing agents** liberate iodine.

**Spiritus**.—**Water** causes a separation of the volatile substance from all of the official spirits except spirit of nitrous ether, spirit of ammonia, whiskey, and brandy. They all contain alcohol, and consequently have the reactions of alcohol.

**Strontium**.—1. Salts of strontium in aqueous solution are precipitated by the soluble **carbonates**, **phosphates**, or **oxalates** as strontium carbonate, phosphate, or oxalate. 2. The soluble **sulphates**, **chromates**, or **alkali hydroxides** precipitate from concentrated solutions the strontium sulphate, chromate, or hydrate.

**Strychnina**.—1. Strychnine combines with **acids** to form salts. 2. Strychnine salts in aqueous solution are precipitated by the reagents mentioned under **ALKALOIDS**, Nos. 2 and 3. 3. In rather strong solutions of strychnine sulphate the soluble **chlorides**, **bromides**, and especially the **iodides** are liable to cause precipitation of the strychnine. The precipitation may not take place for several days. In explaining the cause of the trouble several factors must be taken into consideration. Frequently the commercial samples of the alkali iodides and bromides are alkaline from the carbonate which was left in to aid their keeping, and this alkali would liberate and precipitate the strychnine. The compound which potassium iodide forms with strychnine is only sparingly soluble in water, but the corresponding compounds formed with potassium chloride and bromide are more soluble. Some writers partially explain the precipitation by saying that the compounds formed are less soluble in water containing the

inorganic salts than they are in water alone. Alcohol tends to prevent the precipitation. 4. **Hydrochloric acid** added to a solution of strychnine hydrochloride gives a crystalline precipitate (M. & M., IV. 517). 5. Alkaline substances like **sodium phosphate**, **potassium cyanide**, **sodium arsenate**, **Fowler's solution** and **piperazine** will cause a precipitation when added to an aqueous solution of a strychnine salt. 6. Precipitation by **gold chloride** is prevented to some extent by adding to the gold chloride an equal weight of sodium thiosulphate. [See AURI ET SODII CHLORODI, No. 1.] 7. Strong **nitric acid** if hot converts the alkaloid into the yellow explosive compound which is probably the nitrate of nitrostrychnine (Watts, v. 440). 8. One dram of dilute **nitrohydrochloric acid** with seven drams of water containing one fourth of a grain of strychnine sulphate gives a yellow coloration in a few days. In stronger solutions the change takes place more quickly. The chemical products have not been definitely determined. 9. **Potassium permanganate** in alkaline solution yields ammonia, oxalic acid, carbon dioxide, and another crystalline acid, but in acid solution potassium permanganate gives an amorphous acid with strychnine (M. & M., IV. 517).

**Sulphonethylmethanum**, *Trional*.—1. Trional when triturated with **chloral hydrate**, **euphorin salol**, **thymol** or **urethane** gives a liquid or soft mass.

**Sulphonmethanum**, *Sulphonal*.—1. Sulphonal is not acted upon by alkalies, acids or oxidizing agents. 2. It liquefies when triturated with **chloral hydrate**.

**Sulphur**.—Sulphur readily dissolves in hot aqueous solutions of **hydrates of potassium, sodium, barium, or calcium**, forming polysulphides and thiosulphates. 2. Triturated dry with strong oxidizing agents, as **potassium chlorate** or **permanganate**, explosion is liable to occur. 3. It combines with most non-metallic elements.

**Sulphuris Iodidum**.—1. Iodide of sulphur is decomposed by **alcohol**, **ether**, **volatile oils**, and solutions of **potassium hydroxide** or **iodide**, the iodine being dissolved by these.

**Terebenum.**—1. Terebene on exposure to air and light resinifies and becomes acid. 2. It combines with **chlorine**, **bromine**, and **iodine** to form additive products. 3. In many reactions it resembles oil of turpentine.

**Theobromina.**—1. Theobromine acts like a weak base, and also like a weak acid. 2. It combines with strong **acids** to form salts that are quite readily decomposed by water. 3. It dissolves in an excess of an **alkali hydroxide** solution. 4. From an aqueous solution, theobromine gives a crystalline precipitate with **silver nitrate**, **mercuric chloride**, and **gold chloride**. 5. With many of the general **alkaloidal reagents** it gives no precipitate.

**Thiol.**—Thiol is precipitated from its aqueous solutions by **alkali hydroxides**, **mineral acids**, and **metallic salts**.

**Thymol.**—1. Thymol unites with **alkalies** to form soluble salts (U. S. D., 1250). 2. A solution of thymol with **iodine** and potassium hydroxide gives a red amorphous precipitate of iodothymol (M. & M., IV. 715). 3. **Spirit of nitrous ether** gives a green and then a brown color, changing the thymol to nitroso-thymol. 4. Thymol absorbs **ammonia-gas** and becomes liquid (M. & M., IV. 715). 5. Thymol reduces **gold** and **platinum** from solutions of their salts. 6. **Chromic acid** oxidizes thymol to thymoquinone (M. & M., IV. 715). 7. Thymol gives a liquid or soft mass when rubbed with aristochin, quinine sulphate, trional, and other solids. [See page 267.]

**Thymolis Iodidum, Aristol.**—1. Aristol is decomposed by **light** and **heat**, more quickly if dissolved in ether. 2. It should not be prescribed with bodies that have a strong affinity for iodine, as **oxides**, **hydroxides**, **carbonates**, **starch**, or **mercury salts**. 3. **Oxidizing agents** liberate iodine.

**Tragacantha.**—1. Tragacanth is colored yellow by a solution of **sodium hydroxide** (Allen, I. 428). 2. An aqueous mixture is thickened by **alcohol**, and by **neutral** and **basic lead acetate** (not coagulated by borax, silicates, or ferric salts) (Allen, I. 428). 3. With water and **bismuth subnitrate** it forms masses.

**Urea.**—Urea becomes soft or liquid when triturated with some solids. [See page 267.]

**Zinci Chloridum.**—Zinc chloride, like gold and mercuric chlorides, has a strong tendency to combine with **organic bases**, as strychnine, morphine, and quinine (U. S. D., 1352). [See ZINCUM and ACIDUM HYDROCHLORICUM.]

**Zinci Iodidum.**—1. Commercial zinc iodide frequently does not give a clear solution with water. It is quite distinctly alkaline to litmus and may give a further precipitate when mixed with a solution of zinc chloride.

**Zincum.**—1. Zinc salts in aqueous solutions are precipitated by the fixed **alkali hydroxides** or **lime water** as zinc hydroxide which is soluble in excess of the alkali hydroxide. 2. Zinc salts are precipitated by soluble **carbonates, phosphates, arsenates, or cyanides**, as the basic carbonate, phosphate, arsenate, or cyanide. 3. **Borax** gives a precipitate of zinc borate or a mixture of the borate and hydroxide. 4. **Tannic acid** gives a precipitate with concentrated solutions of zinc salts. 5. Zinc salts coagulate **albumin**.

## PART II.

### *PRESCRIPTIONS WITH CRITICISMS.*

IN studying the following prescriptions the student should try to make out for himself, so far as possible, wherein the trouble lies, and what he would do to prevent or remedy it, before referring to the notes. In order not to overlook any of the incompatibilities it is suggested that he find out what effect, if any, the first ingredient may have on each of the others; then the second ingredient, the third, and so on. Then, taking the prescription as a whole, he should determine the color that will be produced, the nature and color of the precipitate, how one incompatibility will be modified by another, etc. The student should practice translating the Latin into English, and the English into Latin. The majority of prescriptions which follow should be filled, unless in the reaction there is some more active or dangerous compound formed. It must not be forgotten that a variation in the proportions of ingredients modifies the results of combination.

#### 1.

℞  
Hydrargyri chloridi cor., gr. ij  
Potassii iodidi, ℥ ij

## CRITICISMS.

### 1.

When solutions of the first two ingredients are mixed together the insoluble mercuric iodide is formed, and this is redissolved in excess of potassium iodide, forming potassium mercuric iodide, or, as it is commonly known, Mayer's reagent. This compound precipitates the alkaloids of cinchona in the elixir. The alcohol in the elixir is a solvent for this precipitate, but upon addition of the syrup the alcohol is too dilute to exercise much of a solvent effect. The syrup of rhubarb is generally turbid, and it will also cause a precipitation of some of the matter from the elixir of cinchona. The danger in such a prescription is that the patient may take most of the precipitate at one time and thereby get an overdose of the mercuric iodide, which is thrown out of solution with the alkaloids. In 4 fluid ounces of the elixir of cinchona, N. F., there are 7.5 grains of the alkaloidal sulphates. This is more than enough to precipitate all of the mercury, and the prescription should be dispensed with a "shake well" label.

### 2.

There is enough of ammonium carbonate present to neutralize all of the sulphuric acid and liberate the free alkaloid. The quinine sulphate should be dissolved in part of the syrup with the aid of the acid, and the carbonate in the remainder of the syrup. These two solutions should be cooled thoroughly before mixing, because when warm the

free alkaloid collects in sticky masses and it is impossible to get it evenly divided. The effervescence is due to the liberation of carbon dioxide by the acid. If the carbonate is added directly to the acid, the carbon dioxide will escape quickly so that the prescription can be dispensed at once.

### 3.

If the ingredients are powdered separately and then mixed lightly together there will probably be no danger of explosion, and no chemical reaction will take place while the powder is dry. But when taken into the stomach the potassium chlorate with the hydrochloric acid of the gastric juice may oxidize the calomel, forming mercuric chloride. Although this may be considered a rather dangerous prescription it has been filled and taken without apparent ill effect.

### 4.

Chemical reaction takes place between the ammonium carbonate and the acetic acid of the syrup of squills, liberating carbon dioxide. Care must be taken not to cork the bottle until effervescence has entirely ceased.

### 5.

This prescription was filled by dissolving the quinine sulphate in the acid and mixing with the mucilage, and then adding the oil of cloves. The potassium permanganate was dissolved in a little water and added slowly to the other mixture. Dark-brown masses were formed, consisting of coagulated acacia holding in it the manganese dioxide, the permanganate being reduced. It was almost impossible to mix these masses so as to make a homogeneous mixture or

even one that would pour readily. On standing a few hours the manganese dioxide is further reduced to manganous sulphate and the mixture becomes colorless. The patient using this prescription had it refilled several times.

## 6.

The alcohol of the tincture throws the acacia out of solution and the water of the mucilage precipitates the resin from the tincture so that a white precipitate ultimately forms in the bottom of the bottle. A fresh tincture of guaiac with mucilage of acacia gives a blue color but an old tincture gives a brown-red color. With the consent of the physician the prescription was filled by using glycerin and water instead of mucilage. Honey in place of the mucilage keeps the resinous matter suspended better than glycerin does.

## 7.

The sodium hypophosphite is deliquescent in damp air and the powders become moist. Chemical reaction may then take place slowly, causing the mixture to become yellow and finally black. The hypophosphite in acid solution reduces the bismuth to the metallic condition, while the hypophosphite is oxidized to a phosphate. In a neutral or alkaline solution the reaction is slow. The dampening of the extract of nux vomica also tends to darken the mixture. By adding some althæa and using oiled or parchment paper the mixture can be dispensed without difficulty. The directions translated into English are: Mix, make a powder, and divide it into 25 equal parts.

## 8.

The mercuric chloride combines with the sodium and ammonium iodides, forming insoluble mercuric iodide, which redissolves in excess of the alkali iodides, forming a double compound that precipitates some of the constituents of the compound syrup of sarsaparilla. Ammonium iodide very

frequently contains a little free iodine, which probably combines with some of the organic matter present in the syrup. There is no danger of the potassium chlorate liberating iodine from the iodides so long as the mixture is neutral or alkaline. Corrosive sublimate is slowly reduced to calomel by the compound syrup of sarsaparilla (U. S. D., 619).

### 9.

If the first two ingredients are triturated together an explosion is liable to occur. If, however, they be dissolved separately in the water and then mixed there is probably no danger. If the solution were acid chemical reaction would take place with the formation of hydrochloric and phosphoric acids.

### 10.

When these two substances are rubbed together in a mortar with considerable force a damp powder or a soft mass is formed which soon dries. A chemical reaction takes place forming some sodium sulphate and zinc borate, and liberating water of crystallization which causes the dampness. By powdering the ingredients separately and then mixing no difficulty is experienced. The mixture does not make a clear solution in water, a zinc salt being precipitated.

### 11.

This mixture is quite frequently prescribed by physicians, even by those who know that it is incompatible. A chemical reaction takes place between the nitrous ether and the tannin in the buchu, causing an evolution of oxides of nitrogen. Spirit of nitrous ether reacts with an aqueous solution of potassium acetate, giving off a gas, the composition of which has not been definitely determined. The gas must be allowed to escape before corking the bottle. Some of the resinous matter in the fluidextract will be precipitated by the water.

## 12.

The tannin in the tincture of digitalis makes a black inky mixture with the tincture of iron. The phosphoric acid added to the tincture of iron before the two tinctures are mixed partially prevents, or if added after partially destroys, the inky color, the final mixture being dark brown and turbid. If two drams of dilute phosphoric acid be added to the tincture chloride of iron the mixture becomes entirely colorless, due to the formation of ferric phosphate, and on the subsequent addition of a tannin solution the black color is not produced. A little light-colored precipitate is formed.

## 13.

The quinine sulphate and the lead acetate react, forming quinine acetate and lead sulphate, both of which are practically insoluble in the syrup. The bismuth subnitrate is also insoluble. In filling this prescription it is best to add about twenty grains of powdered tragacanth to aid in suspending the insoluble substances. A "Shake well" label should be put on the bottle.

## 14.

Alum, being a soluble sulphate, will react with the lead acetate, precipitating the insoluble lead sulphate according to the following equation:

The precipitate should not be filtered out.

## 15.

The tannic acid combines with the quinine, forming the nearly insoluble quinine tannate. This prescription should be filled by dissolving the quinine sulphate in a part of the

syrup with the aid of the sulphuric acid. The tannic acid should be dissolved in the remainder of the syrup and this gradually added to the other solution with constant stirring. Both solutions should be cold, because if mixed when warm the precipitate formed is sticky and will make a mass that cannot be evenly divided.

### 16.

Emulsify the cod-liver oil by adding it in portions to the lime water in a bottle. Then add the oil of wintergreen, the syrup, and the syrup iodide of iron. The calcium hydroxide of the lime water saponifies a small amount of the cod-liver oil, which soap helps to emulsify the balance of the oil. When the syrup of ferrous iodide is added to the mixture containing the calcium hydroxide ferrous hydroxide is precipitated. Ferrous hydroxide if free from ferric hydroxide is white, but it quickly oxidizes to ferroso-ferric hydroxide, which varies from a dirty green to almost black. After some time it is oxidized to a yellow-brown basic ferric oxide. This prescription will go through these various colors.

### 17.

Donovan's solution precipitates many alkaloids from aqueous solutions of their salts. Quinine is no exception. This prescription was filled by dissolving the quinine sulphate in most of the syrup with the aid of the acid; dissolving the potassium iodide in the remaining syrup and adding to the first solution. Donovan's solution was then slowly added with constant stirring and the prescription sent out with a "Shake well" label. The danger in such a prescription does not come from the quinine which is precipitated, but the mercuric salt which is precipitated with the quinine. In concentrated solutions of quinine potassium iodide gives a precipitate. At the end of two days all of the mercury was precipitated and some iodine was liberated, the sulphuric acid displacing the hydriodic acid and the air oxidizing the hy-

driodic acid. Any quinine not precipitated by the Donovan's solution was precipitated by the iodine.

### 18.

There is not a sufficient amount of water to dissolve all of the quinine sulphate. If the sodium salicylate is dissolved in part of the syrup and the quinine is mixed with the balance of the syrup and these two brought together a bulky gelatinous precipitate of quinine salicylate is formed. The resulting mixture is so thick that it can be poured only with difficulty. When a little sulphuric acid is used to aid the solution of the quinine sulphate, or when quinine bisulphate is used, the precipitate of quinine salicylate subsequently formed is generally more bulky and tenacious.

### 19.

The mercuric chloride precipitates the strychnine sulphate as a double compound, which is soluble in a fairly strong alcohol, less soluble in the presence of hydrochloric acid. This prescription deposits a precipitate of long needle-shaped crystals on standing a few hours, but not immediately on filling. If the first ingredient is omitted no precipitation takes place within at least twenty-four hours, although there is danger of precipitation after the patient has received it. The addition of a few drops of hydrochloric acid quickly brings it down. If the mercuric chloride be omitted there will be but little danger of precipitation. This prescription as written should not be filled, because of the precipitation of strychnine and also because of the large dose of strychnine.

### 20.

If the first two ingredients are dissolved in separate portions of the elixir and then mixed a clear solution results. This, however, becomes turbid in a few minutes, and the liquid separates into two layers, the upper one having somewhat of an oily appearance. This oily liquid is chloral alco-

holate, formed from the chloral hydrate and the alcohol of the elixir. Just what part the potassium bromide takes in the reaction seems not to be well understood, unless it be to render the alcoholate less soluble in the elixir. Other inorganic salts, such as sodium bromide or sodium chloride, act in a similar way. If there is not more than about ten grains of chloral hydrate and ten grains of potassium bromide in a dram of the solution there is but little danger of the chloral alcoholate separating. Chloral alcoholate is more soluble in alcohol than it is in water, and by the addition of a little more alcohol the separation of the two fluids can sometimes be prevented. This prescription when filled as written may be considered a dangerous one. Several cases have been reported where alarming symptoms have been caused by the taking of a teaspoonful of chloral alcoholate. On filling a similar combination, if a turbidity results the mixture should be kept until it can be determined whether there will be a separation into two layers, and if so, then remedied by adding a little alcohol or putting on a "Shake well" label.

## 21.

In solution lead subacetate with zinc sulphate gives a precipitate of lead sulphate; a precipitate of lead tannate with the compound tincture of catechu; a precipitate of the opium alkaloids with the laudanum. Zinc sulphate is precipitated as the tannate by the compound tincture of catechu. The tannic acid in the compound tincture of catechu precipitates the opium alkaloids. Water precipitates resinous matter from the tinctures. The exact reactions will vary with the method of filling. This prescription should be dispensed without filtering but with a "shake well" label.

## 22.

Mercuric chloride combines with albumin to form a compound insoluble in water. The presence of an equal weight or more of sodium or ammonium chloride prevents to a considerable extent the formation of the precipitate. "By

dissolving one part of corrosive sublimate and a hundred parts of common salt in distilled water and evaporating to dryness a soluble double preparation is obtained which does not coagulate albumen." (U. S. D., 619.) If this prescription were filled as directed it would be practically inert. By adding three or four grains of ammonium chloride to the mercuric chloride, dissolving this in about one half the water and the albumin in the remainder of the water, and mixing these solutions, a nearly clear solution can be obtained.

23.

Sodium phosphate requires 5.5 parts of water to dissolve it; consequently in this prescription it would not be all dissolved. It should be powdered before adding to the syrup and water and the prescription then dispensed with a "Shake well" label. Sometimes a powdered crystalline salt with water makes a crystalline mass in the bottle.

24.

The syrup of garlic contains acetic acid, which combines with the ammonium of the ammonium carbonate, liberating carbon dioxide. The reaction should be completed before the bottle containing the solution is corked, or the pressure of the gas formed may be sufficient to burst the bottle.

25.

The zinc is entirely precipitated by the borax, producing a white flocculent precipitate of zinc borate or a mixture of the borate with a basic compound. The prescriber should be advised of this fact. If the prescription is dispensed the precipitate should be filtered out. The amount of glycerin necessary to decompose the borax and neutralize the alkalinity is more than would be allowable.

26.

The spirit of nitrous ether is generally acid in reaction, and when an acid solution of nitrous ether is brought in con-

tact with potassium iodide, iodine is liberated and the gas nitric oxide is formed. This prescription should not be filled on account of the free iodine formed.

## 27.

Several chemical reactions occur, depending on the order of mixing the ingredients. The possible reactions are as follows: 1. The potassium iodide in the compound tincture of iodine when mixed with a solution of ferric chloride forms free iodine, potassium chloride, and ferrous chloride. 2. Fowler's solution is alkaline, due to the presence of potassium bicarbonate and perhaps some normal potassium carbonate. This carbonate neutralizes part of the free hydrochloric acid when mixed with the tincture of iron, forming potassium chloride and carbon dioxide. 3. Ferric chloride with phosphoric acid forms the colorless ferric phosphate, which is insoluble in water, but soluble in water containing free acid. 4. Tincture chloride of iron dissolves quinine sulphate, the free acid of the tincture combining with the quinine sulphate to form a more soluble compound. 5. The iron combines with tannic acid in the rhubarb, forming the black tannate of iron. 6. The free iodine in the compound tincture of iodine combines with sulphate of quinine, forming an insoluble compound. 7. The free iodine will also combine with the tannin in the rhubarb. 8. The alkali in Fowler's solution will neutralize part of the phosphoric acid when mixed with it. 9. The alkali in Fowler's solution when mixed with a solution of quinine sulphate combines with the sulphuric acid, liberating and precipitating the free alkaloid. 10. The phosphoric acid is a solvent for quinine sulphate, probably combining with it and under certain circumstances again precipitating it. 11. A solution of quinine sulphate is precipitated by the tannic acid of the rhubarb, forming the insoluble tannate of quinine.

In whatever way the ingredients are mixed the combination is an extremely inelegant one; it is black and inky in

color and taste, and the quinine and rhubarb are not in solution.

### 28.

Pure ferric pyrophosphate of iron is insoluble in water. The official soluble pyrophosphate of iron may be a double compound of sodio-ferric citro-pyrophosphate, or it may be a mixture of ferric pyrophosphate and sodium citrate, the former being soluble in a solution of the latter. When sulphuric acid is added to the solution of this compound or mixture the ferric pyrophosphate is precipitated, the sulphuric acid probably combining with the sodium and liberating citric acid. The quinine is not precipitated.

### 29.

This makes a clear brownish-red solution, which on standing two or three days loses much of its color. The color varies with the proportion of free iodine which also varies with the condition of the soap liniment. Soap, oil of rosemary, and camphor all reduce the iodine to some extent. In some cases all of the iodine is changed so that it no longer gives a test with starch. The products formed are not well known.

### 30.

An old specimen of bismuth and ammonium citrate is generally not entirely soluble in water unless a little ammonia water is added. At best the solution of this salt is usually slightly alkaline, and the pepsin on being added to this is rendered inert by the alkali. If, however, the hydrochloric acid is used in dissolving the pepsin in water and this solution added to the bismuth and ammonium citrate dissolved in the balance of the water, the action of the pepsin will not be destroyed, but a precipitation will take place. This precipitate is bismuth citrate, the hydrochloric acid breaking up the double salt and combining with the ammonia. Pepsin should

not be prescribed with bismuth and ammonium citrate, as one or the other loses much of its activity. When such a prescription is to be filled it is best to dissolve each ingredient separately, making each solution neutral before mixing them.

### 31.

When the sulphurous acid is added to the solution of the sodium hypophosphite in the cinnamon water a turbidity results, due to the separation of free sulphur. The hypophosphite is oxidized to a phosphate and the sulphurous acid is reduced to sulphur. In the presence of a very large excess of the hypophosphite the sulphur is further reduced to hydrogen sulphide.

### 32.

Potassium iodide is hygroscopic in a moist atmosphere and powders containing it usually become damp. There is no reaction between calomel and potassium iodide if the mixture is dry, but mixed in the above proportions in the presence of moisture a dark-gray powder is produced. Mixed in more nearly equal proportions a yellowish-green powder is formed. Chemical reaction takes place, with the formation of potassium chloride and mercurous iodide, which is yellow. The mercurous iodide is decomposed by the excess of potassium iodide, forming metallic mercury and mercuric iodide and then potassium mercuric iodide; it is the metallic mercury that gives the mixture the gray color. This prescription should not be dispensed, because of the oxidation of the mercurous compound to the much more active mercuric compound, or if it is, the dose should be reduced to correspond with that of the mercuric salt. The directions are: Mix, make a powder, and divide into 10 powders (papers).

### 33.

If the acid is added to the tincture a red coloration is formed at contact of the two liquids. This red color quickly

changes to an orange and then to a yellow when the liquids are mixed. The changes in color are probably due to the action of the acid on the brucine. If now the mixture is allowed to stand a short time a chemical reaction is evidenced by the evolution of bubbles of gas. This reaction continues slowly for several hours, and is due to the acid acting on the organic matter other than the alkaloids, probably tannin. The dilution with the elixir does not prevent it. On adding the acid or the elixir to the tincture a precipitate of inert matter is produced.

### 34.

There is not enough of water to dissolve all of the quinine sulphate, as it requires 720 parts of water. The water will precipitate inert extractive matter from the tincture. While potassium iodide does not always precipitate strychnine sulphate when in solution with it, there is some danger of precipitation. (See the incompatibilities of strychnine.) The usual maximum medicinal dose of strychnine sulphate is  $\frac{1}{12}$  of a grain. In this prescription the dose is  $\frac{5}{16}$  of a grain and is dangerously large. The prescription should not be dispensed without first having called the prescriber's attention to that fact, as well as to the possibility of the strychnine being precipitated by the potassium iodide.

### 35.

The wine of pepsin of the National Formulary contains hydrochloric acid and the syrup of ipecac contains acetic acid. There is a sufficient amount of ammonium carbonate to neutralize both of these acids and render the solution alkaline, thereby destroying the activity of the pepsin. In the reaction carbon dioxide is given off and the bottle must not be corked until the reaction is complete, for the pressure of the gas might burst the bottle.

## 36.

If the directions to rub these solids together be followed an explosion will probably result. Potassium chlorate forms an explosive mixture with each of the three other ingredients. Each substance should be powdered separately and all mixed together lightly. Some pharmacists would decline to fill this prescription. If filled, however, the patient should be informed of the nature of the mixture and cautioned to keep it where there will be no danger of its receiving a blow between two hard surfaces.

## 37.

If these ingredients are mixed together and allowed to stand the oil of turpentine will rise to the top. The oil should first be emulsified with the syrup and about forty-five grains of acacia and then the other liquids added. When water is added to paregoric the oil of anise and the benzoic acid are precipitated, but these would be held in suspension by the emulsion. Sometimes the solution of ammonium acetate is alkaline, there having been an excess of ammonium carbonate or a deficient amount of acetic acid used in making it. In such a case the acid in the syrup of squills will liberate carbon dioxide.

## 38.

Evidently the prescriber wished to air a little of his knowledge or then had some kind of an agreement with a certain pharmacist to fill his prescriptions. It is unusual to employ the chemical symbols in writing prescriptions, and it can hardly be expected that the dispenser will know and remember such complicated formulas as the first one and of a compound which is used comparatively seldom.  $C_{18}H_{21}NO_3$  is codeine, KI is potassium iodide,  $C_3H_8O_3$  is glycerin, and  $H_2O$  is water.

This prescription was filled by dissolving the codeine in

the glycerin and part of the water. The iodide was dissolved in the remainder of the water and the two solutions mixed, without any precipitation occurring at once. After several days, however, there was a deposit of very fine crystals. Potassium iodide precipitates quite a number of the alkaloids from their solutions. This precipitation can be prevented by having a small amount of alcohol present.

### 39.

The potassium chlorate is soluble in about 16 parts of water; consequently only a small proportion is dissolved in the three ounces of water. Some pharmacists would contend that the excess of the chlorate in a powdered condition should be left in the bottle, so that the patient could add water to it as the liquid was used up. This might be all right if it were a simple mixture of the chlorate and water. But in the above prescription, since the fluids are all more or less medicinal, it is evident that the physician wanted only a saturated solution of the chlorate and the excess removed. The resinous matter of the tincture is precipitated by the water. The fluid *hydrastis* colorless is a preparation which seems to vary much in composition. The U. S. Dispensatory gives a method of making it which consists in dissolving twenty grains of *hydrastine* sulphate in one pint of a mixture of equal parts of glycerin and water.

### 40.

The *copaiba* when mixed with the tinctures does not make a clear solution, as it requires from three to four times its amount of alcohol, although it is readily soluble in absolute alcohol. On the further addition of glycerin the mixture was made more turbid and the syrup when added threw out of solution most of the *copaiba*, which had been dissolved by the alcohol of the tinctures. On standing the *copaiba* rises to the top, but the syrup and glycerin are viscid enough to

hold it in suspension for some little time, so that the patient can get a uniform dose. It should be dispensed with a "Shake well" label.

41.

When the first two ingredients are rubbed together the liquid chloral camphor is formed. This will not dissolve all of the cocaine hydrochloride for which the prescription calls. 5 Dg. is 5 dekagrams or 50 grams, which is undoubtedly a mistake. The prescriber probably meant 5 dg., which is 5 decigrams or one half of a gram. That being the case, the cocaine can be readily mixed with the oily liquid, but to get it into solution the free alkaloid should be used.

42.

Strong nitric acid decomposes creosote, with the formation of red fumes. Dilute nitric acid converts it into a brown resin. (U. S. D., 404.) In filling this prescription the nitric acid should be slowly added to the creosote with constant stirring. A considerable heat is generated by the reaction, and the mixture should be allowed to cool before adding the chloroform, so that it will not be volatilized. It is doubtful if this prescription has much caustic effect.

43.

Chloral hydrate is decomposed by alkalies, forming chloroform and a formate of the base. Borax is sufficiently alkaline so that chloroform will be slowly generated and can be recognized by the odor, but not enough is formed to do any harm.

44.

There is considerable danger of having an explosion in attempting to fill this, although it has been dispensed many times. If the potassium chlorate is rubbed with the glycerin

explosion is liable to take place. Or if the chlorate be added to the solution of ferric chloride, which always contains some free hydrochloric acid, chlorine will be formed, and this will act upon the glycerin, converting it into oxalic and carbonic acids. In filling this the temperature should not go above 70° F., and then the bottle should be loosely stoppered for a time before giving to the patient. The chlorate is not entirely dissolved.

#### 45.

The amount of chlorine formed will depend upon the order of mixing the ingredients. If the potassium chlorate and hydrochloric acid are mixed and then the water added a yellow liquid containing much free chlorine with oxides of chlorine will result. If, however, the salt is first dissolved in water and then hydrochloric acid added the amount of chlorine formed will be small. The physician has not indicated which was wanted, but probably the latter, as the former would be exceedingly irritating.

#### 46.

The usual maximum dose of the tincture of lobelia is two drams, which is the amount called for here. The doses of the other two tinctures are rather large, although not above the maximum. A three-ounce mixture is obtained without using any of the compound syrup of squills at all. Probably the physician intended to have omitted to "q. s. ad," thus making a six-ounce mixture.

#### 47.

No change is noticed in the appearance of this mixture on standing unless exposed to sunlight when it becomes a dirty gray. The odor is still prominent at the end of a month. According to the U. S. D. the odor of the iodoform slowly diminishes, due to the decomposition caused by the tannic acid.

## 48.

On triturating these two substances together the mixture becomes black. Ammonium carbonate acts like ammonium hydroxide, forming metallic mercury and a mercuric salt. [See *HYDRARGYRI CHLORIDUM MITE*, No. 3.] If all of the calomel is thus decomposed there would be over six grains of the mercuric compound and the amount taken in one capsule would be a dangerous dose.

## 49.

The dose of potassium cyanide is dangerously large, the usual maximum dose being about one fourth of a grain. The physician, knowing that morphine acetate frequently is not entirely soluble, has directed the use of acetic acid. The excess of acid combines with the potassium, liberating hydrocyanic acid. The potassium cyanide frequently contains a carbonate as an impurity, and in such case might neutralize the free acid and precipitate some of the free morphine. In neutral solutions the potassium cyanide precipitates morphine cyanide from morphine salts. Morphine cyanide is soluble in acid solutions. The prescription should not be filled without consulting the prescriber.

## 50.

The alcohol in the spirit and tincture precipitates and ferric chloride gelatinizes the mucilage of acacia. The gelatinous mass will slowly dissolve in the syrup on standing. The best way to fill the prescription is to dilute the tincture with part of the syrup and mix the rest of the syrup with the spirit and then these with the mucilage. In this way the gelatinization is avoided.

## 51.

Several chemical reactions are possible in filling this prescription, depending upon the order of mixing the ingredients. If the potassium bicarbonate is added to the syrup of lemon carbon dioxide will be liberated by the citric acid. Spirit of nitrous ether is usually acid with nitrous and nitric acids, and these will liberate the carbon dioxide if brought in contact with the bicarbonate. The solution of potassium hydroxide is capable of neutralizing the acid in the spirit or part of that in the syrup. The spirit of nitrous ether if added directly to the fluidextract will cause a reaction, with the evolution of red fumes. This will not take place as readily if the solution of potash is added to the fluidextract first. Some of the resinous matter in the fluid extract is precipitated by the syrup. The gas which is formed should be allowed to escape before corking the bottle; otherwise an "explosion" might result.

## 52.

This prescription resembles Blaud's pills, inasmuch as the potassium carbonate reacts with ferrous sulphate in the presence of moisture to form the green ferrous carbonate. This ferrous carbonate oxidizes in the air, forming ferric oxide, and to prevent this some sugar should be added. The potassium carbonate with mercuric chloride gives the red-brown oxychloride of mercury, and with strychnine sulphate it gives the free alkaloid. As the mixture is to be made into pills, and the compounds formed are not more active than those prescribed, there need be no hesitation about filling the prescription. It may be filled by following the general directions in the U. S. P. for making Blaud's pills. The mass is strongly alkaline.

## 53.

If these three ingredients are mixed in the absence of moisture no change in appearance is noticeable. In the presence of moisture the mixture at once begins to turn gray. This is due to the formation of metallic mercury and mercurous oxide, while at the same time some mercuric chloride is formed (M. R., VII. 492). The sodium bicarbonate seems to play some part in the reaction since calomel and antipyrine with water do not readily darken. This might be considered a rather dangerous prescription, but probably there is not enough of the mercuric salt formed to cause dangerous symptoms.

## 54.

On standing the citric acid in the syrup combines with the sodium, liberating salicylic acid, which, being only sparingly soluble in water, is precipitated in needle-shaped crystals. This can be dispensed as a shake mixture. The precipitation is rather tardy, and it would be well to inform the patient of the change which will take place.

## 55.

Reaction takes place between the potassium iodide and the ferric chloride, forming free iodine, ferrous chloride, and potassium chloride. Potassium iodide and spirit of nitrous ether react, forming free iodine and nitric oxide. Gentian is said to contain no tannin, but the other drugs with which it is combined in the compound tincture do. The tannin combines with the iron to form the black inky ferric tannate. This prescription should not be dispensed on account of the free iodine formed. The iodine is not precipitated.

## 56.

If the solution of dialyzed iron has been improperly made and is strongly acid no precipitation occurs. But if it is nearly neutral, as it should be, ferric hydroxide is precipitated

by the alkali that is in Fowler's solution. The ferric hydroxide forms with the arsenic an insoluble compound of basic ferric arsenite, which to some extent changes to ferrous arsenate. Though liquid at first the mixture may gelatinize after several days.

### 57.

Giving but a glance at this prescription we would conclude that it should not be dispensed, that the strychnine would be precipitated. But upon closer study we find that the solution of strychnine, B. P., is an acid hydro-alcoholic solution containing about one per cent. of strychnine hydrochloride. On adding sodium bicarbonate to this the hydrochloric acid combines with it, and the strychnine is liberated, but not precipitated. Strychnine (free alkaloid) is soluble in about 6700 parts of water. In this prescription we have only about .015 Gm. in 100 Cc., or 1 part to 7500 of water, a sufficient amount of water to keep the alkaloid in solution.

### 58.

In making Fowler's solution the excess of potassium bicarbonate used is changed to the carbonate by boiling and the carbonate makes the solution alkaline. Potassium carbonate precipitates a solution of mercuric chloride as the basic mercuric chloride. In this prescription there may be a red-brown precipitate of the oxychloride of mercury but more generally a white precipitate of calomel forms. An arsenite in an alkaline solution reduces mercuric chloride to mercurous chloride and in excess to metallic mercury. Had the prescriber used the solution of arsenous acid instead of potassium arsenite no trouble would have resulted. The compounder should neutralize the Fowler's solution with hydrochloric acid before adding to the solution of mercuric chloride.

### 59.

On dissolving the quinine sulphate in part of the cinnamon water with the aid of the sulphuric acid, then adding the

potassium acetate previously dissolved in the remainder of the water, a voluminous precipitate of quinine acetate is obtained. Quinine acetate is only sparingly soluble in water, and the amount here formed is so large and bulky that it is difficult to pour out an even dose. By using one half of a dram of dilute sulphuric acid a thinner mixture is obtained.

#### 60.

Different results are obtained, according to the order of mixing the ingredients. If the Fowler's solution is added to the solution of dialyzed iron ferric hydroxide is precipitated, and this combines with the arsenic to form an insoluble basic ferric arsenite. But if the syrup is added to the iron and the Fowler's solution is diluted a little with water and then added to the iron, little or no precipitation takes place. Sugar to some extent acts as a solvent for the ferric hydroxide. Solution of dialyzed iron varies considerably in the amount of acidity which it has; if properly made it is nearly neutral. Some samples are sufficiently acid to prevent any precipitation by Fowler's solution. There is some danger of the strychnine being precipitated by the alkali in the Fowler's solution. Syrup or water added to the tincture of cinchona causes a turbidity. The tannin in the tincture will make a black mixture with the iron. To avoid the precipitations noted above the solution of potassium arsenite should first be neutralized with hydrochloric acid; or a better way would be to get the prescriber to use the solution of arsenous acid instead of potassium arsenite. The directions translated into English are: Mix. Label: Let a teaspoonful be taken after dinner.

#### 61.

The dose of aconitine is entirely too large unless the particular sample to be used has been proved to be comparatively inert. Two and one half grains of a so-called aconitine have been taken without ill effects, while  $\frac{1}{128}$  of a grain has been reported to have caused death. The commencing

dose of absolute aconitine should not be much over  $\frac{1}{600}$  of a grain. In this prescription there are several physiological incompatibilities. In action aconitine is more or less opposed to morphine, strychnine, and belladonna. Morphine is to some extent antagonistic to atropine and strychnine, and atropine to strychnine.

62.

This makes a clear colorless solution at first. In a day or two it acquires a yellow color which deepens. The products formed have not been determined. A similar prescription containing glycerin is sometimes written, and it does not change in color so readily.

63.

The mercuric chloride and ferrous iodide react to form mercuric iodide and ferrous chloride. The insoluble red iodide of mercury thus formed is redissolved in the excess of ferrous iodide. The creosote requires 150 parts of water for solution. In this case there is an excess of creosote, and it forms an oily layer on top unless it is emulsified. Occasionally the solution of ammonium acetate is alkaline, and in such a case it might give a precipitate with the mercuric chloride, forming ammoniated mercury, and with the ferrous iodide, forming ferrous carbonate.

64.

The ingredients of this prescription can be mixed so as to make a homogeneous mass, but on standing for a few days the balsam separates from the petrolatum. This can be prevented by incorporating one and a half drams of simple cerate or of lanolin in place of a like amount of petrolatum. The odor of iodoform is gradually lost, due, according to the U. S. D., 662, to the formation of a new compound. Rubbing the balsam with lard for a few minutes the mass gets granular and then the resinous matter seems to stick together and the lard is worked out.

## 65.

This gives a clear solution at first but after a day or two a precipitate is formed. The precipitate gives a test for both arsenic and iodine. There may be an oxy-iodide of arsenic formed. If this mixture is dispensed at all it should be with a "Shake well" label. Adding two drams of water does not entirely prevent precipitation.

## 66.

The euphorin, aristol, tannic acid, and alum can be triturated together, producing a powder. On adding the crystallized carbolic acid to this mixture, it becomes very soft, almost liquid. This change is the result of bringing carbolic acid in contact with the euphorin, these two substances liquefying when triturated together. The mass with the oil of theobroma makes a mixture too soft to be made into suppositories. Carbolic acid alone has a softening effect on the oil. In summer it is necessary to render it firmer by the addition of wax, spermaceti, or some absorbing powder, as starch or slippery elm or by standing.

## 67.

Although the sulphuric acid aids the solution of the quinine sulphate, it precipitates the glycyrrhizin of the fluid-extract. The glycyrrhizin, thus precipitated as glycyrrhizic acid, loses much of its sweet taste and no longer disguises the taste of the quinine. It would have been better if the prescriber had omitted the sulphuric acid and directed a shake mixture. The water causes the separation of a small amount of inert matter from the fluidextract.

## 68.

Several chemical reactions take place, depending upon the manner of filling this prescription: 1. Between the hydrochloric acid in the tincture and the potassium chlorate, liberating chlorine. 2. The chlorine thus formed may act upon

the glycerin or alcohol. 3. Between the hydrochloric acid and the ammonia and glycyrrhizin in the fluidextract, precipitating the glycyrrhizic acid. 4. Between the iron and tannic acid in the fluidextract, giving the black tannate of iron.

### 69.

The dose of the arsenic and of the strychnine is between  $\frac{1}{7}$  and  $\frac{1}{8}$  of a grain in this prescription. The maximum dose of each, as generally given, is not over  $\frac{1}{10}$  of a grain. The prescriber should be consulted. Moreover, each pill would contain about seven grains of medicinal matter, which, considering the bulky quinine sulphate and extract of gentian, makes a very large pill. Where such a large pill is prescribed, twice as many pills are sometimes made as directed and then the number to be taken at one time is doubled.

### 70.

Water can be added to carbolic acid, forming a clear solution. On adding more water the acid separates as an oily liquid, going to the bottom. When water has been added so that the proportion is about 1 part of acid to 15 parts of water, a clear solution again results. In this prescription there will be a layer of liquefied acid in the bottom of the bottle. If the brush should remain in the bottle between the periods of using it, there is danger that it will become saturated with the strong acid and that the patient will apply it in this condition. By the use of two drams of glycerin in place of part of the water a clear solution can be made, and this is what the dispenser should use.

### 71.

Filled as written this prescription makes a thick mixture that will run, and on standing a liquid separates. The amount of starch should be cut down to one third or one fourth of the amount

and then boiled with the lime water. By so doing a much smoother ointment is made and there is practically no separation of liquid.

## 72.

Different results may be obtained by changing the order of mixing these ingredients. If the corrosive sublimate is dissolved in the water and then added to the lime water the yellow mercuric oxide is precipitated. This if mixed with the mucilage and allowed to stand for some time changes to a dirty-brown color. If the lime water is added to the solution of mercury the red-brown basic chloride of mercury is precipitated. If the solution of mercuric chloride is added to the mucilage of acacia and then the lime water added to this no precipitation of mercury takes place. On allowing this to stand for a few days a flocculent precipitate is formed, slowly increasing. Acacia prevents the precipitation of a number of the heavy metals by the alkaline hydroxides.

## 73.

The bismuth subnitrate is insoluble in the syrup, but a chemical reaction takes place between it and the hydriodic acid, as is evidenced by the change in color. Bismuth subnitrate is white; on mixing it with the syrup the color becomes yellow and quickly turns to a grayish black. According to Watts' Dictionary, the oxyiodide of bismuth is copper-colored and the bismuth iodide is a brilliant gray.

## 74.

Sodium bromide on being exposed to the air attracts moisture. Pepsin is somewhat hygroscopic if contaminated with peptones. Pepsin is rendered inert by alkalies, as sodium bicarbonate.

## 75.

The sodium phosphate of the U. S. P. is the  $\text{Na}_2\text{HPO}_4$  and is slightly alkaline to litmus. This alkalinity may cause precipitation of the strychnine, and it should be neutralized with a little phosphoric acid before the solutions of sodium phosphate and strychnine sulphate are mixed.

## 76.

If the turpentine is poured upon the iodine violent chemical reaction results, with the formation of violet fumes of vaporized iodine, caused by the heat generated. While there is not enough of alcohol to dissolve all of the iodine, it is best to dissolve as much as possible before adding the turpentine, which should be added in small portions, cooling the mixture if necessary. Upon standing the liquid separates into two layers, the lower one, being much smaller in amount, is the alcohol. Turpentine and alcohol are not miscible in all proportions.

## 77.

According to the National Formulary, Hall's solution of strychnine contains  $\frac{1}{8}$  of a grain of strychnine acetate to the dram, together with some acetic acid. Fowler's solution contains, besides the potassium arsenite, some potassium bicarbonate or carbonate (formed by the boiling of the bicarbonate in water). This carbonate will react with the acetic acid, liberating a little carbon dioxide and forming potassium acetate. If there is an excess of the alkaline carbonate the strychnine will be liberated as the free alkaloid. The strychnine will not be precipitated, however, as it is soluble in 110 parts of alcohol, and the prescription can be filled without difficulty.

## 78.

The resinous matter in the tincture of myrrh is precipitated by the syrup. By adding the tincture to the syrup in small portions and shaking well after each addition the resin comes down in a form in which it can be more readily suspended in the liquid. Tannic acid combines with the morphine to form a compound insoluble in water. On standing the precipitated matter forms into masses, rendering an even dosage difficult. Using one or two drams of honey in place of that much syrup helps to keep the precipitated matter finely divided.

## 79.

In filling this prescription each of the salts was dissolved in separate portions of water. The potassium iodide solution was added to the mercuric chloride solution, and at first there was a red precipitate of mercuric iodide, which was dissolved by the further addition of the potassium iodide, forming the soluble potassium mercuric iodide. On the addition of the ammonium carbonate solution to this no change of any kind was noticed. However, when the ammonium carbonate solution was added to the mercuric chloride solution a white precipitate of ammoniated mercury was formed. On adding the potassium iodide solution to this mixture the precipitate disappeared and a clear nearly colorless solution was formed. Probably the ammoniated mercury was decomposed and the soluble double compound of potassium mercuric iodide was formed.

## 80.

When the ingredients of this prescription are mixed the liberation of iodine commences at once and continues for some time. The wine and spirit were mixed and neutralized with ammonia, thinking thereby to prevent the formation of

iodine, but with practically no benefit. The hypophosphorous acid in the syrup is not sufficient to prevent the liberation of iodine. Filled as written the iodine is precipitated in time, and also a brown flocculent precipitate is formed. The prescription should not be dispensed.

81.

This mixture in a short time becomes yellow and within twenty-four hours it changes to a light brown. The coloration is due largely to the action of the nitrous acid on the morphine. Less change takes place if the mixture is neutral. The morphine is converted into nitroso-morphine, pseudo-morphine, and another base (M. & M., III. 436).

82.

Although this ointment is brown at first it becomes blue and then greenish black, due to the ichthyol and iodine.

83.

The pharmacist who received this prescription in attempting to fill it rubbed the three ingredients together dry and caused an explosion, whereby he was quite severely injured. The explosion was due to the reaction between the chlorate and hypophosphite. The pills can be made by powdering the ingredients separately, then mixing lightly with powdered extract of liquorice and massing with water.

84.

Iodine is soluble in about 10 parts of alcohol. As much of the iodine as possible was dissolved in the alcohol and then the camphor dissolved in this. This solution was then gradually added to the mercurial ointment with constant

trituration and the water was added last. On standing a few minutes a red precipitate was formed and the mixture separated into three layers. In the bottom was this red precipitate, probably mercuric iodide, then a layer of fatty matter, and on top a hydro-alcoholic fluid containing free iodine. This mixture was such that it could be shaken up and applied. On the third day the red precipitate had disappeared, leaving the yellow fatty matter and a fluid somewhat red and containing a little free iodine. Seven days later the liquid was yellowish brown and contained only a trace of iodine. Part of the iodine probably combined with the mercury to form mercuric iodide, and part was probably reduced to a soluble iodide, which dissolved the mercuric iodide. Another part of the iodine probably combined with some of the camphor and fatty matter. Although the activity of the iodine is very much diminished the mixture is decidedly active on account of the mercuric salt formed.

#### 85.

Creolin is said to be an emulsion of cresol, obtained by means of resin soap. It forms a milky emulsion or mixture with water. This prescription may be filled by dissolving the acid in the water and adding the creolin slowly with constant shaking. Part of the creolin separates on standing, but it may be readily mixed by agitation. As this is an eye-lotion and not clear, an attempt was made to filter it, but with the result of separating nearly all of the creolin. It should be dispensed with a "Shake well" label.

#### 86.

The citric acid should be dissolved in the boiling water and then the magnesium carbonate added to this. Carbon dioxide is liberated and magnesium citrate goes into solution. The addition of borax does not cause any precipitation, al-

though the solution is alkaline. If the borax is added to the solution of citric acid and then the magnesium carbonate a large amount of the last ingredient is not dissolved, the acid having been nearly neutralized by the borax.

## 87.

Gold and sodium chloride precipitates the sulphates of atropine and strychnine and the alkaloids in cinchona. There is about thirty per cent. of alcohol present but not enough to prevent precipitation. By dissolving the gold and sodium chloride in water and adding an equal weight of sodium thio-sulphate a compound is formed that does not precipitate the alkaloids from this mixture. The gold may be reduced on standing for some time. Water precipitates inert matter from the fluidextract. Atropine and strychnine are somewhat antagonistic in their physiological action.

## 88.

In medium-sized medicinal doses morphine and atropine are physiologically incompatible. But the minute dose of atropine in this prescription assists rather than diminishes the action of morphine by relieving the cardiac depression, indigestion, and constipation.

## 89.

The pharmacist should not use the excipient directed. Potassium permanganate is easily reduced by organic matter, which it in turn oxidizes. Some excipient must be chosen that will not reduce the permanganate. A mixture of equal parts of petrolatum, paraffin, and kaolin makes a good one, or wool-fat with kaolin may be used. When filled as written no permanganate could be detected at the end of a week.

## 90.

The oil of turpentine reacts with the acids, with the generation of much heat, and unless care be taken it will be ignited. The acids should be mixed and cooled and then added in small portions to the oil, cooling after each addition. The alcohol should be added last, after the mixture is cold, so as to avoid volatilization.

## 91.

On mixing the acid with the bicarbonate in the presence of water effervescence takes place, due to the liberation of carbon dioxide; a nearly colorless quite strongly alkaline solution results. If this is allowed to stand undisturbed for two or three days the lower part of the liquid will be of a light-brown color and the upper part of a dark brown, and finally it will become dark brown throughout. An aqueous solution of a salicylate turns dark when exposed to the air, probably on account of the formation of some oxidation products. This change takes place much more quickly when the solution is alkaline. If the physician had prescribed sodium salicylate instead of the salicylic acid and sodium bicarbonate he would have gotten practically the same physiological effect (unless he wanted the effect of the alkali too), made a better preparation pharmaceutically, and saved the pharmacist considerable time and work. The patient should be informed of the change of color that will take place.

## 92.

This can be filled by dissolving the alkaloidal salts in the syrup of lemon and tincture of iron, adding the water, and then the phosphoric acid last. The solution is clear and of a pale reddish color previous to the addition of the acid. After the addition of the acid the solution becomes colorless and

slightly turbid and in a few minutes a heavy precipitate is formed. The three disturbing causes are tincture of iron, phosphoric acid, and quinine sulphate, leaving out any one of which prevents precipitation. If the amount of quinine is reduced to three grams there is but little precipitation and none if it is reduced to two grams. The decoloration is due to the formation of ferric phosphate, which is insoluble in water but soluble when there is an excess of free acid. By using enough of dilute sulphuric acid to dissolve the quinine in water no precipitation results.

### 93.

When this prescription is filled as written a crystalline precipitate forms at once. Both Fowler's solution and potassium iodide precipitate the strychnine. Neutralizing Fowler's solution will prevent its causing trouble, but there will still be danger from the potassium iodide precipitating the strychnine.

### 94.

The first two ingredients when mixed give a greenish-brown solution, which when diluted with water gives a deep-blue color and largely diluted gives a violet color. On adding the sulphurous acid the color is destroyed within a few minutes. The ferric chloride is reduced to the ferrous chloride and sulphate, and a ferrous salt does not give a coloration with carbolic acid. If the sulphurous acid is added direct to the tincture of ferric chloride a deep-red solution of ferric sulphite is formed, which changes to ferrous sulphate and becomes colorless. Adding the carbolic acid to this gives no coloration. It makes little or no difference what order is observed in filling this prescription.

## 95.

Ferrous sulphate usually contains some ferric sulphate and this reacts with the calcium hypophosphite to form ferric hypophosphite and calcium sulphate, the former being only sparingly soluble, and the latter requiring 380 parts of water for solution. Part of the sulphuric acid of the Epsom salt will go to form calcium sulphate. In an acid solution the potassium chlorate would have an oxidizing effect on the ferrous sulphate and also on the hypophosphite; in this prescription it probably has but little chemical action. The solution of strychnine is a British preparation containing about one per cent. of strychnine hydrochloride. Potassium chlorate and a hypophosphite should not be triturated together dry, as they form an explosive mixture.

## 96.

This mixture makes a clear alkaline solution, colorless at first, but in a few minutes acquiring a light-brown color, which slowly becomes dark red brown or almost black. This coloration is due partly to the alkaline salicylate acquiring a red color in the air, and partly to the effect of action of the spirit of nitrous ether upon the salicylate. Prof. Attfield suggests the formation of nitrosalicylic acid which is colored. The change does not take place quite as rapidly when the spirit is mixed with the carbonate previous to the dissolving of the sodium salt. Generally the spirit of nitrous ether is acid, and when ammonium carbonate is added to it carbon dioxide is given off.

## 97.

This was filled in several ways, the result being the same. The codeine was triturated with a little water and a half dram of dilute phosphoric acid added to dissolve the alkaloid. The hydrocyanic acid was next added, and then the tincture of iodine, which did not precipitate the alkaloid, but was itself

decolorized at once. The further addition of the water simply diluted the solution.

If the tincture of iodine is added to the solution of codeine in water and phosphoric acid a reddish-brown precipitate is formed, consisting of codeine and iodine. This precipitate is not dissolved by adding an excess of phosphoric acid or sulphuric acid, but the twenty minims of dilute hydrocyanic acid dissolves the precipitate and makes a clear colorless solution. The explanation is that the hydrocyanic acid reduces the iodine to an iodide and thus breaks up the compound of codeine and iodine. Other reducing agents, as sodium hyposulphite, have a similar effect.

98.

Reaction takes place between the calcium hydroxide and the mercurous chloride, forming calcium chloride and the black mercurous oxide. This is similar to the "black wash" of the National Formulary.

99.

The best way to fill this prescription is to dissolve the corrosive sublimate in the glycerin mixed with a half dram of water. Then to this solution add *all at once* the syrup of lime. A yellow precipitate is formed at first, but this quickly disappears and a clear slightly yellowish liquid results. A slight light-gray precipitate is formed after standing a day, and this increases slowly for several days. Certain organic substances, such as glycerin, sugar, and gum arabic, have the power of preventing the precipitation of solutions of some of the metallic salts by alkali hydroxides.

If the syrup of lime is added slowly to the solution of corrosive sublimate a yellow precipitate is formed, but is redissolved again when the water is added. Quite a heavy steel-gray precipitate forms within an hour and it slowly increases on further standing. A similar result takes place if the solution of mercuric chloride is added to the syrup of lime.

## 100.

Free bromine is formed if the potassium bromide is added to the tincture and the free bromine combines with antipyrine. If the bromide is dissolved in water and then added to the tincture of iron previously diluted with water no bromine is liberated. Antipyrine gives an intense red coloration with the tincture of iron.

## 101.

The compound tincture of iodine was official in the 1870 Pharmacopœia and contained iodine and potassium iodide dissolved in alcohol. Reaction takes place between the gold chloride and the potassium iodide. "Potassium iodide, added in small portions to a solution of auric chloride (so that the latter is constantly in excess where the two salts are in contact), and when equivalent proportions have been reached, gives a yellow precipitate of aurous iodide,  $\text{AuI}$ , insoluble in water, soluble in large excess of the reagent; the precipitate is accompanied with separation of free iodine, brown, which is quickly soluble in small excess of the reagent as a colored solution. But on gradually adding auric chloride to solution of potassic iodide, so that the latter is in excess at the point of chemical change, there is first a dark-green solution of potassio-auric iodide,  $\text{KIAuI}_3$ ; then a dark-green precipitate of auric iodide, very instable, decomposed in pure water," forming the yellow aurous iodide. (Prescott and Johnson's *Qualitative Chemical Analysis*, 4th ed., 154.) Probably the organic matter present also tends to the reduction and precipitation of the gold. The physician should be notified of the change which takes place. Only a very small amount of menthol is dissolved.

## 102.

The usual maximum dose of the fluid extract of digitalis is two minims, some authorities giving it as high as three.

In this prescription it is about three and a half minims. Taking into consideration the frequency of the dose and that digitalis is cumulative, the pharmacist should decline to fill it until he has consulted the prescriber, or ascertained that it is an urgent case.

### 103.

No apparent change takes place at first but in less than four hours a yellow-brown precipitate of metallic gold forms. The arsenous acid reduces the gold chloride. It is also easily reduced by many other inorganic compounds as well as by organic matter and light.

### 104.

Tincture of iron if not too strongly acid will give a color varying from a blue to a dirty green with morphine. This color is destroyed by excess of acid or by alcohol. This prescription will give a bluish-green mixture, which will turn to a yellowish orange in a day or two. This latter change is probably due partly to the slow formation of chlorine by the action of the hydrochloric acid in the tincture on the potassium chlorate. Chlorine turns a morphine solution orange color. There is not enough water to dissolve all of the chlorate.

### 105.

Sodium bromide precipitates the codeine salt, ammonium chloride does not. The phenacetin is not dissolved. The mucilage will keep the codeine and phenacetin suspended so that the prescription can be dispensed as a shake mixture.

### 106.

If the sulphate of iron is strictly ferrous, no liberation of iodine takes place when a solution of potassium iodide is added to it, but most of it contains some ferric salt which liberates iodine. If the morphine is now added it will be

precipitated by the iodine. The solution of ferrous sulphate gradually deposits a precipitate of subsulphate of iron. Or if the solution of ferrous sulphate and the morphine are mixed before adding the potassium iodide no free iodine is formed, the morphine seeming to reduce the ferric sulphate to ferrous.

### 107.

In massing these two chemicals with an excipient containing water reaction takes place, with the liberation of carbon dioxide, which causes the mass to swell to several times its original size. This reaction goes on slowly, requiring several hours for completion, and the mass should not be made into pills until the reaction has been completed. By using glycerite of starch little or no trouble is experienced.

### 108.

If the ingredients are powdered separately and are perfectly dry when mixed no chemical reaction takes place. The powder will keep for months if protected from moisture. On the addition of water the powder at once becomes dark gray in color. The darkening is due to the formation of metallic mercury; at the same time some mercuric salt is formed, which with the excess of potassium bromide forms a compound soluble in water. This is a dangerous prescription and should not be dispensed unless the dose is reduced. If the reaction takes place according to the equation given below, each powder will contain about three and eight-tenths grains of mercuric salt.

### 109.

Bismuth subsalicylate is white, insoluble in the solution and remains suspended for a few minutes. The insoluble matter turns yellow in a few hours, and yellow brown in a few days, continuing to get darker. Some gas is slowly evolved, probably due to the reaction between the hydrogen dioxide and tannic acid.

## 110.

This mixture gives a nearly black precipitate and a brown-black liquid. Several experiments were made to determine what agents caused the change. The hydrogen dioxide glycerin, and water showed no change on standing several days but when a mixture of these contained zinc sulphate it acquired a yellow to a yellow-brown color and became turbid after some time. A mixture of carbolic acid, hydrogen dioxide, water and zinc sulphate begins to color in a few minutes, getting brown black by the next morning. A precipitate forms and increases on standing. Hydrogen dioxide is said to oxidize carbolic acid to pyrocatechin and hydroquinone and to oxidize glycerin to glyceric, oxalic, and tartaric acids. Just what part the zinc sulphate played in this prescription was not determined. It perhaps acted only as a carrier or perhaps as a decomposer of the hydrogen dioxide.

## 111.

This mixture is permanent in a dry atmosphere, but in a damp one it absorbs moisture. Either in the presence of absorbed moisture or when taken into the stomach several reactions are liable to take place. Lead sulphate would be formed from the lead subacetate and morphine sulphate. The sodium bicarbonate would react with each of the other three ingredients, forming with bismuth subnitrate, bismuth subcarbonate and carbon dioxide; with lead subacetate, lead carbonate; with morphine sulphate, the free alkaloid. Lead subacetate would also combine with the morphine to make a compound insoluble in water. These incompatibilities do not make a dangerous mixture, and there is no reason for declining to fill it.

**112.**

Triturating the iodol with the mercuric oxide caused an explosion, which might have been avoided by mixing the ingredients separately with portions of petrolatum and then mixing these.

**113.**

A mixture of these ingredients sometimes becomes soft and sticky in a short time and again it may remain in a powder for days. The condition of the atmosphere seems to cause the variation. "The reaction between sodium salicylate and antipyrine, thought to be due to chemical change, is simply due to deliquescence." (Nat. Dispensatory, 5th ed., 227.) This explanation is hardly satisfactory, since either chemical alone is not hygroscopic. By putting these ingredients into capsules separately without previous mixing they in time become soft and liquid, but not before the prescription would ordinarily be used. The capsules might be dispensed in a bottle.

**114.**

This was filled by dissolving the sodium bicarbonate, borax, salicylic and benzoic acids in water. The thymol and menthol were rubbed together until a liquid resulted; then the eucalyptol, the glycerin, and the oil of wintergreen were added. To this was added the first solution. After allowing the mixture to stand an oily liquid separated, rising to the top. Effervescence is due to a reaction between the bicarbonate and the salicylic, benzoic, and boric acids, the latter being formed by the action of glycerin on borax. (See No. 141.) Eucalyptol makes a clear mixture with glycerin, but is separated on the addition of water. The oily liquid formed by the menthol and thymol does not make a clear solution with glycerin, nor does the oil of wintergreen; and whatever of these may have

been dissolved by the glycerin is thrown out of solution by the water. A " Shake " label is necessary.

### 115.

The quinine sulphate was dissolved in a part of the water with the aid of the acid. The potassium iodide was dissolved in the balance of the water and added to the quinine solution. Iodine is gradually formed by the acid acting on the iodide, and this combines with the quinine, forming a dark-brown precipitate.

### 116.

Basham's mixture contains acetic acid and an acetate. The quinine salt dissolves in this, but within a few minutes it is thrown down as a bulky crystalline quinine acetate. The mixture is so thick that it would be difficult to pour out an even dose. Replacing quinine sulphate with the bisulphate does not help.

### 117.

Borax is alkaline in reaction and precipitates the hydrastine as the free alkaloid, and also precipitates the alkaloids from the tincture of opium. The boric acid is not sufficient to neutralize the alkalinity of the borax. As the preparation is to be dropped into the eye, it should be filtered, and in so doing nearly all of the hydrastine is removed. The physician's attention should be called to this, and he be advised to increase the amount of acid or decrease the borax or, what is better, leave out the latter. Boric acid does not give a precipitate with a solution of hydrastine sulphate. Or, the prescription can be filled by adding five to seven drops of glycerin directly to the borax, mixing well, adding part of the water, then the other ingredients. Water precipitates a little resinous matter from the tincture.

## 118.

When these ingredients were mixed a clear solution resulted, which was of a light-yellow color at first, but within five minutes became green. On allowing this to stand no change in color took place until the third or fourth day, when it acquired a greenish-brown color, and by the sixth day it had lost all green and was of a brownish-red color; further standing changed it to a deep red.

It has been proved that ethyl nitrite or amyl nitrite or any substance containing nitrous acid forms with antipyrine the green isonitroso-antipyrine, which crystallizes out of concentrated solutions. At one time it was thought that this green compound was poisonous, but it is not now generally considered so. [See ANTIPYRINA, No. 19.)

## 119.

The quinine sulphate was dissolved in part of the water with the aid of the acid. When the solution of potassium iodide in the balance of the water was added to the quinine solution a slight precipitation occurred. This granular precipitate, which falls quickly, is potassium bitartrate, formed by the reaction between the potassium iodide and the tartaric acid. That it is not the quinine that is precipitated can be proved by substituting sodium iodide for potassium iodide, when no precipitation takes place. In concentrated solutions potassium iodide precipitates quinine. Hydriodic acid, formed by the action of tartaric acid on potassium iodide, is easily decomposed by the air, liberating iodine which precipitates the quinine. When this mixture is allowed to stand for two or three weeks without being disturbed two layers in the precipitate are noticed, the bottom one is white and is the potassium bitartrate, while the upper one is red-brown and is the iodine compound of quinine. The addition of a few minims of dilute hypophosphorous acid will retard the liberation of iodine. The directions are: Mix. Label: Let a teaspoonful be taken two or three times a day.

## 120.

When the spirit of nitrous ether is added to the resorcin dissolved in the water and glycerin a dark-red solution is formed. This is perhaps due to the formation of dinitroso-resorcin (or possibly mononitroso-resorcin), which crystallizes in yellowish plates. Using a spirit that has been neutralized with sodium carbonate seems to make no difference. Ammonia turns this solution a deep blue.

## 121.

Salicylic acid, being only sparingly soluble, is brought into solution with the aid of sodium phosphate, which is alkaline. The salicylate gives a deep red color with the iron, due to ferric salicylate.

## 122.

These ingredients make a clear dark-red solution, which changes to a red-straw color within five minutes. The red color is due largely to the tincture of iodine. Iodine with ammonia in excess forms chiefly ammonium iodide with a little ammonium iodate, so that in this prescription, so far as physiological effect is concerned, it would be about as well to use some ammonium iodide instead of tincture of iodine. At the end of twenty-four hours the mixture was strongly alkaline and still slightly colored.

In a mixture of ammonia and iodine there is some danger of the violently explosive iodide of nitrogen being formed, more especially where the iodine is in excess. This iodide of nitrogen is insoluble and is slowly precipitated as a dark-brown solid.

## 123.

This prescription makes at first a clear solution, which gives a precipitate on standing a short time. If the tincture of iron is not strongly acid the precipitate is yellowish brown. The precipitate was filtered out and washed with water until the washings no longer gave a test for iron. It was

then dissolved in dilute sulphuric acid; the solution was not fluorescent or bitter; on adding ammonia water it gave a heavy red-brown precipitate of ferric hydroxide. From this it was supposed that the original precipitate was a basic salt of iron which had been thrown out of solution by the quinine taking some of the hydrochloric acid from the tincture to form a more soluble quinine salt.

If, however, some hydrochloric acid is added to the tincture before adding the alkaloidal salts, or the tincture is quite strongly acid, or quinine bisulphate is used the solution deposits prismatic crystals. These crystals dissolve readily on addition of water, and are probably a quinine salt separated out from a super-saturated solution. The pharmacist in dispensing the prescription should see that the tincture is quite strongly acid. The physician should also give his consent to allow the solution to be diluted with water with an increase in the dose.

#### 124.

This solution is bluish red in color. No chemical reaction occurs except that the salicylic acid occurring as methyl salicylate in the oil of wintergreen combines with the iron to form a salicylate of iron, which gives the increase of color. By adding the water gradually to the iron a play of colors is noticed: first yellow, then red, dark red, and finally violet-red.

#### 125.

Salol and thymol triturated together make a liquid. When the other ingredients are added the mass is still much too soft to be made into pills. If a sufficient amount of liquorice root is added to make the mass of the required consistency the pills are too large to be taken easily. If the soap and extract of liquorice are omitted and in their place one dram of magnesia and one dram of kaolin are used a fair mass is made. Even then the pills are large and it is better to make twice the number of pills and double the dose.

## 126.

On mixing solution of protargol and cocaine hydrochloride a precipitate is produced in a few hours and precipitation goes on slowly for several days. Saturating the water with boric acid seems to retard the precipitation. The precipitate in suspension has a grayish color, but when settled it is of a bluish purple. The liquid has a blue fluorescence like quinine sulphate.

## 127.

Several reactions may occur when the first two ingredients are mixed, depending upon the proportions. A mercuric oxychloride is formed by the carbonate of potassium in the Fowler's solution. Under certain circumstances mercuric arsenite is formed and is dissolved in a solution of potassium arsenite. In the presence of an alkali, arsenites reduce mercuric compounds to mercurous compounds and then to metallic mercury, and the arsenites are oxidized to arsenates. In this prescription a pinkish-white precipitate is first formed, consisting of calomel and the coloring matter of Fowler's solution. On further standing it turns dark, due to the reduction to metallic mercury. Fowler's solution added to the quinine sulphate liberates the free alkaloid. If the prescriber had directed the solution of arsenous acid instead of potassium arsenite there would have been no reduction and but little precipitation.

## 128.

The ammonia water combines with the acid in the tincture of iron, forming ammonium chloride and ferric hydroxide. The precipitation of the ferric hydroxide may be prevented by mixing the glycerin with the tincture before adding the ammonia. If the ammonia is added to the tincture and then the glycerin the precipitated ferric hydrate dissolves but slowly in the glycerin. Glycerin, as well as sugar, acacia, honey, and some other organic substances, prevents or hinders the precipitation of many of the metals by alkali hydroxides.

## 129.

Ferric salts gelatinize mucilage of acacia, and if the solution of dialyzed iron is added directly to the mucilage a solid mass results, which dissolves slowly in the syrup. By diluting the solution of iron with the syrup, and then adding this slowly to the mucilage with constant stirring, a thick homogeneous liquid may be obtained. [See ACACIA, Nos. 2 and 3.]

## 130.

“According to M. Mialhe, calomel is partly converted into corrosive sublimate and metallic mercury by ammonium chloride and by sodium and potassium chlorides, even at the temperature of the body.” (U. S. Dispensatory, 17th ed., 695.) This is not now generally considered a dangerous prescription. [See HYDRARGYRI CHLORIDUM MITE, No. 7.] The directions are: Mix and divide into 20 equal parts. Label: Take one two or three times a day.

## 131.

Spirit of nitrous ether with acetanilide gives a yellow solution, becoming red on standing for some time. The color occurs more quickly with an acid spirit than with a neutral one, and the presence of a little sodium bicarbonate prevents it for several weeks. Probably diazo-compounds are formed.

## 132.

Amyl nitrite and potassium iodide in the presence of an acid give free iodine, nitric oxide, and amyl alcohol. The prescription should not be dispensed as written. As from the directions—“Let it be dispensed quickly”—it seems to be an urgent case, and in all probability the effect of the amyl nitrite is what is wanted, the potassium iodide should be omitted. At the very first opportunity the physician should be informed of the omission.

## 133.

The first three ingredients were mixed and the Epsom salt dissolved in the water and the two solutions mixed. A turbidity occurred at once, due to the precipitation of extractive matter from the alcoholic liquids by the water. Within a few hours the magnesium sulphate had crystallized out so that its bulk was nearly one half of that of the mixture. Magnesium sulphate, being insoluble in alcohol, is thrown out of its aqueous solution by the alcohol of the fluidextracts and the tincture. This cannot be prevented except by diminishing the magnesium sulphate or increasing the proportion of water. If the mixture is made up to one pint with water the magnesium salt is not thrown out of solution.

## 134.

Iodine is soluble in 10 parts of alcohol and 60 parts of glycerin; nearly insoluble in water. The first two ingredients mix, making a clear solution, but water precipitates the iodine if the tincture of the 1890 Pharmacopœa is used. The present formula contains potassium iodide, and iodine is soluble in a solution of an iodide.

## 135.

Mucilage of acacia is necessary in this prescription. Heroine is precipitated by corrosive sublimate, solution of potassium arsenite, and ammonium carbonate. Mercuric chloride is precipitated as calomel by the arsenite and as ammoniated mercury by the ammonium carbonate.

**136.**

When calomel and cocaine hydrochloride are triturated together a gray mixture results. Probably a part of the calomel is reduced to metallic mercury, which gives the gray color, and another part is oxidized to mercuric chloride. As the amount in each pill of the mercuric chloride formed is within the limits of the dose of that substance, the pills may be dispensed. It would be well, however, to inquire the age of the patient and the frequency of the dose. By the addition of about five grains of starch or liquorice root and a little water a suitable pill-mass can be made, the pepsin giving sufficient adhesive qualities.

**137.**

This is a very common combination. Lead subacetate forms compounds with nearly all alkaloids, and these are insoluble in water. The opium alkaloids are no exceptions. The alcohol undoubtedly tends to prevent the precipitation to some extent, though there is still quite a heavy one. The lead is also precipitated by the meconic and sulphuric acids in the opium. The precipitate should not be filtered out but the mixture should be dispensed with a " Shake well " label.

**138.**

Filled as written the white bismuth subnitrate is soon changed to a black precipitate. Using more hydrochloric acid, the darkening takes place sooner and leaving out the acid no darkening results for several days. The hydrochloric acid liberates hypophosphorous acid from the hypophosphites and the hypophosphorous acid reduces the bismuth to the metal.

**139.**

When silver oxide and creosote are triturated together there is great danger of an explosion. It has been proposed

to mix the creosote with powdered soap and then with the oxide, which has been previously mixed with liquorice root. The mass should not be rubbed hard and should be kept cool.

#### 140.

The tannic acid in the tincture combines with the quinine to make the insoluble nearly tasteless quinine tannate. The water precipitates the resinous matter from the tincture. A "Shake well" label should be put on the bottle.

#### 141.

In filling this prescription there will be an effervescence, due to the generation of carbon dioxide. It is not caused by the carbolic acid and sodium bicarbonate, as might be supposed. Glycerin in the presence of water decomposes borax, forming sodium metaborate and boroglycerol. Water reacts with the boroglycerol to give glycerin and boric acid. The boric acid with sodium bicarbonate gives sodium borate and carbon dioxide. Other polyhydric alcohols, such as mannitol, dextrose, levulose, and glucose, act like glycerin in decomposing borax. The chemical reactions which take place may be represented by the following equations:

#### 142.

Carbon dioxide will be generated by the sulphuric acid and the potassium bicarbonate. There is a sufficient amount of the bicarbonate to neutralize all of the acid and also to liberate quinine as free alkaloid, which is nearly insoluble. It will also liberate ammonia from the ammonium carbonate in the aromatic spirit of ammonia used as the menstruum in making the tincture. Resinous matter and the oils in the

tincture are thrown out of solution by the water. Tincture of guaiac if freshly prepared colors acacia blue.

**143.**

Spirit of turpentine is another name for oil of turpentine. Oil of turpentine is easily oxidized and nitrohydrochloric acid is a strong oxidizing agent, so that there is quite a violent reaction when the two are brought together. Even though the oil is emulsified first, chemical change cannot be avoided. Supposing that the prescriber wanted a four-ounce mixture, the dose of the acid would be about thirteen minims. The maximum dose, as given in the U. S. Dispensatory, is six drops. The excessive dose would be sufficient to prohibit the filling of this prescription. In such a case where the prescriber could not be notified many pharmacists would use the dilute nitrohydrochloric acid instead of the concentrated.

**144.**

The potassium permanganate was dissolved in part of the water and the glycerin was diluted with the balance of the water; the two solutions were then mixed. Within two minutes the mixture was of a brownish-black color and almost solidified by the manganese dioxide that was formed. After standing the precipitated manganese dioxide settled, leaving a clear colorless solution, showing that the permanganate was all reduced. When potassium permanganate and concentrated glycerin are brought together there is some liability of the mixture exploding or flaming. The oxidation products of the glycerin are probably formic, propionic, and tartronic acids; in an alkaline mixture oxalic and carbonic acids are formed.

**145.**

The potassium citrate was dissolved in the syrup and the spirit was then added. The two liquids were mixed, produc-

ing a turbidity, and on standing separated into two distinct layers. Potassium citrate is hygroscopic, but nearly insoluble in alcohol. The alcohol of the spirit has a tendency to throw the citrate out of solution, but the salt has such an affinity for water that it carries some water with it, forming a solution not miscible with alcohol.

#### 146.

The aromatic spirit of ammonia contains ammonium hydroxide and ammonium carbonate, and these act similarly in precipitating the corrosive sublimate as ammoniated mercury ( $\text{NH}_2\text{HgCl}$ ). Ammoniated mercury is soluble in solutions of ammonium salts and somewhat soluble in acids, so that the sulphuric acid in the infusion will redissolve it, though not very readily. The precipitation may be prevented by mixing the infusion and spirit together first. Mercuric chloride precipitates the cinchona alkaloids from their aqueous solutions when not too dilute. The oils in the spirit are thrown out of solution by the water of the infusion. The directions are: Mix. Label: Teaspoonful twice a day.

#### 147.

Triturating the alum with the lead acetate produces a moist sticky mass. This is due to the chemical reaction which takes place, forming lead sulphate, aluminum sulphate, potassium acetate, and liberating the water of crystallization which makes the mixture sticky. A mass is obtained when zinc sulphate and lead acetate are rubbed together. In either case the odor of acetic acid is noticeable. When the mixture is put into water the tannic acid will precipitate the lead, if any remains not combined with sulphuric acid, as lead tannate. The other two salts are not so readily precipitated as tannates. In filling this prescription the water of crystallization may be removed by heating, or the ingredients may be powdered separately and then mixed lightly, and no difficulty will ensue.

**148.**

The difficulty with this prescription is that triturating the salicylic acid with the exalgine produces a soft sticky mass which is unfit for dispensing in powders. Even by mixing all of the other ingredients except the acid and adding it last and then mixing lightly on paper the mixture becomes sticky. By diluting the acid with twice its weight of powdered althæa and then with the other ingredients a fair powder can be obtained. Probably the best way would be to put the ingredients into capsules, separating the acid from the exalgine by the phenacetin and cocaine, if the mixture is to be used internally.

**149.**

This makes a mixture which is very thick at first, but yet can be poured. Allow it to stand for half an hour and it solidifies; by the end of twelve hours it is so firm that it cannot be shaken in the bottle. Even if only one half of the amount of magnesia is used the mixture will solidify so that it cannot be shaken up if allowed to stand undisturbed for a day or two. By vigorous shaking several times the mass can be broken up so that it can be poured. Magnesium oxide takes up water to form the gelatinous magnesium hydrate. The alkalies all tend to prevent the precipitation of the resinous matter in the tincture by the water.

**150.**

Several chemical reactions will take place, depending upon the order of mixing. The possible reactions are as follows: 1. Ferric iron is reduced to ferrous iron, giving at first a red solution of ferric thiosulphate. 2. The hydrochloric acid of the tincture reacts with the thiosulphate, forming sodium chloride, sulphurous acid, and sulphur. 3. With potassium chlorate, the sulphurous acid thus formed gives potassium sulphate, hydrochloric and sulphuric acids. 4. Hydrochloric

acid with potassium chlorate gives potassium chloride, water, chlorine, and several oxides of chlorine. 5. The chlorine thus formed oxidizes the reduced ferric salt back to the ferric condition and oxidizes the hyposulphite to a sulphate.

There is not enough water to dissolve all of the chlorate, and after the reactions have taken place there is not enough acid to form a normal ferric salt of all of the iron; a part of it remains as an insoluble oxychloride.

### 151.

Quinine sulphate and hydrobromic acid give a slight greenish color. By hydrobromic acid a part of the mercurous chloride is reduced to metallic mercury, and a part is oxidized to mercuric chloride, which is much more active than calomel. By adding the calomel last the reaction can be prevented to some extent, and the amount of mercuric chloride formed is probably not dangerous. The directions are: Mix and divide into 10 equal parts and put into gelatin capsules. Label: One capsule to be taken every three hours.

### 152.

Commercial dilute hydrocyanic acid usually contains some free sulphuric or hydrochloric acid, which has been added to preserve the hydrocyanic acid. If one of these mineral acids is present an effervescence will take place. Hydrocyanic acid itself does not decompose carbonates (Prescott and Johnson's Qualitative Chemical Analysis, 4th ed., 308). Hydrocyanic acid easily decomposes in water, but in an alkaline solution its decomposition is much quicker, giving a formate and a dark-colored precipitate containing paracyanogen.

## 153.

Triturating salol and monobromated camphor together produces a liquid. But if the acetanilide and salol are rubbed together first and then the camphor added a damp powder is obtained. If about fifteen grains of powdered soap are then added and a little drying powder if necessary, a mass can be made, the pills becoming hard in an hour or two.

## 154.

The order of mixing these ingredients makes a difference in the products first formed, but after standing the results are probably similar. If the solution of zinc chloride and the lime water are mixed a white precipitate of zinc hydroxide is formed, and there is no change in appearance on adding the mercuric chloride dissolved in the water.

If, however, the mercuric chloride solution is added to the lime water the yellow oxide of mercury (yellow wash) is precipitated. On adding the zinc chloride solution and allowing it to stand the precipitate is changed within two hours from a dense yellow to a flocculent white precipitate.

If the lime water is added to the solution of mercuric chloride a red-brown precipitate of oxychloride of mercury is formed, and this is replaced by a white precipitate when the zinc chloride is added.

That the lime water precipitates nearly all of the mercuric chloride when these two chemicals are brought together in the above proportions is evidenced by taking some of the clear supernatant liquid and passing hydrogen sulphide gas through it and getting little or no black precipitate of mercuric sulphide. If some of the clear solution is taken after the zinc chloride has been added and the yellow precipitate turned white, and this solution is treated with hydrogen sulphide, a heavy black precipitate of mercuric sulphide is pro-

duced, showing that the mercuric oxide has been dissolved and the zinc precipitated. Owing to the fact that the mercury is in solution, this prescription might be dangerous if applied in large amounts to an abraded surface, since if all of the mercury is redissolved it will be in the proportion of about 1 to 500.

### 155.

Piperazine is strongly alkaline and when added to an aqueous solution of phenocoll hydrochloride precipitates the insoluble base phenocoll. Under certain circumstances, as when the phenocoll hydrochloride is from fifty to one hundred per cent. in excess of the piperazine, a clear solution is said to be obtained. This prescription was filled by dissolving the phenocoll hydrochloride in the elixir, syrup, and peppermint water, and the piperazine in the water. The two solutions were mixed, making a clear solution, which remained clear for two days. It then happened to be chilled at night and crystallization took place, making an almost solid mass, which remained so even at the ordinary temperature. On warming a solution resulted, which remained clear at the ordinary temperature, but again solidified on being chilled.

### 156.

The ammoniated tincture of guaiac if it has not been exposed too long to light and air gives a blue color with the tincture of iron, but an old tincture of guaiac gives a brown-black. The tincture of aloes gives a green-brown to a black-brown with the iron. There is not enough of ammonia in the ammoniated tincture of guaiac to form the ferric hydroxide unless the tincture of guaiac is freshly made with a fresh aromatic spirit of ammonia and the tincture of iron is free from excess of acid. Even then the syrup will tend to keep the ferric hydroxide in solution. The syrup precipitates the resinous matter from both tinctures. The resulting mixture is nearly black and very turbid.

## 157.

The dose of the morphine sulphate is considerably in excess of the amount usually given. The prescriber shows his knowledge and appreciation of this fact by putting three exclamation-points after the ingredient. The prescription should be filled as written. Some physicians when wishing to give unusual doses underscore the ingredient and the quantity. The latter is perhaps a better method, as there is less danger of a mistake. The directions are: Mix. Dispense in 10 capsules. Label: Let one be taken during the night.

## 158.

On mixing these ingredients a blue-black solution is obtained. This is due to the presence of some ferric sulphate. Ferrous sulphate as found in drug-stores nearly always contains some ferric sulphate. If strictly ferrous sulphate is used tannic acid gives no coloration with it.

This prescription was filled by dissolving the clear crystals of ferrous sulphate in water, adding four grains of sodium thiosulphate and two drops of sulphuric acid, and boiling until all of the ferric iron was reduced to the ferrous, as shown by adding a drop of this solution to a solution of potassium sulphocyanide and getting no red color. The tannic acid was dissolved in another portion of water, the syrup added, and this added to the iron solution. A colorless liquid was obtained, astringent but not inky in taste. In three days the solution had assumed a green color and in ten days it was blue-black. This change, caused by the oxidation of the iron by the air, would have taken place sooner if the bottle had been opened frequently.

## 159.

This prescription can be filled in one of two ways. The chloral hydrate may be dissolved in the water, and the camphor powdered and mixed with the syrup and then with the

solution of chloral. The camphor will rise to the top. Or the camphor may be triturated with the chloral hydrate until liquefied, and this shaken with the syrup and water. The oily chloral-camphor does not dissolve in the water, but seems to be decomposed by it, the chloral going into solution and the camphor coming to the top as a soft white solid. There seems to be no difference in the final result as to which method of filling is used. In either case the mixture is a difficult one to pour so as to get an even dose of the camphor. A more elegant preparation would be made by dissolving the camphor in a little expressed oil of almonds and then emulsifying it with acacia.

### 160.

On adding the phosphoric acid to a solution of the iron and quinine citrate a white precipitate forms which gives tests for iron but not for quinine. It is probably iron phosphate and is soluble in a considerable excess of the acid. When the dilute phosphoric acid is further diluted with water and then added to the iron salt dissolved in the balance of the water with the syrup, little or no precipitation takes place. When the tincture is added to this, a turbidity results and the mixture acquires a dark green color, due to the precipitation of matter from the tincture and the formation of tannate of iron.

### 161.

In lightly mixing the first two ingredients when powdered and perfectly dry no change in color is noticed; triturated together with considerable pressure, the powder turns gray. As soon as moisture comes in contact with the mixed powders they become dark gray—the coloration is due to the formation of metallic mercury—while at the same time a part of the calomel is changed to mercuric chloride and mercuric cyanide. (See No. 192.) A translation of the latter part of the prescription is: Tragacanth, water, of each a quantity suffi-

cient to make a mass which is to be formed into 30 pills. Label: Take two pills every night.

**162.**

Soluble metallic salts frequently throw the volatile ingredient of medicated or aromatic waters out of solution. In this case there will be a separation of camphor, which will rise and float on top. The amount is so small that it may be disregarded or filtered out.

**163.**

The Rochelle salt throws some of the camphor out of solution. Then on the addition of the aromatic sulphuric acid the turbidity is increased on account of the separation of the oil of cinnamon and the resin of ginger. Chemical reaction takes place between the Rochelle salt and the sulphuric acid, the sodium sulphate going into solution and potassium bitartrate being precipitated.

**164.**

Fowler's solution is alkaline in reaction and has a tendency to precipitate the alkaloids from the fluidextract, but this is prevented by the alcohol in the elixir. The Fowler's solution contains some carbonate and bicarbonate of potassium, which are said to be incompatible with antipyrine. Ammonium iodide generally contains a little free iodine, and iodine combines with antipyrine. Practically, however, this prescription can be filled without difficulty or danger.

**165.**

Strychnine (free alkaloid) is soluble in 6400 parts of water. There is enough of water and alcohol in the elixir to prevent the aromatic spirit of ammonia from throwing it out of solution. The ammonia will not precipitate the alkaloids of the

elixir of cinchona. The above mixture will not be clear, however, because the oils in the aromatic spirit will be separated by the elixir. If the spirit of ammonia were used instead of the aromatic spirit a clear dark-red solution would be obtained. This substitution would not be allowable without the prescriber's consent.

166.

All of the ingredients except the syrup can be mixed without producing much turbidity. But on adding the syrup to this mixture the resinous matter from the fluid-extract and tincture is precipitated, and the copaiba, oil of turpentine, and camphor are separated. To make a presentable mixture some emulsifying agent must be used.

167.

This mixture makes a solid mass and cannot be applied with a brush. A gelatinous mass which possibly might be applied with a brush is obtained when one half of the collodion is replaced by alcohol.

168.

If the Fowler's solution is added to the tincture of nuxvomica the alkali in the solution will liberate the free alkaloid strychnine, but it will be held in solution by the alcohol until the infusion is added. With the addition of most infusions the alkaloids would be precipitated, but the infusion of cinchona contains sulphuric acid, which combines with the alkaloids, forming a soluble salt. The water of the infusion will precipitate some of the inert matter from the tincture.

169.

When solution of lead subacetate is added to mucilage of acacia a solid gelatinous mass is formed. In this prescrip-

tion if both are diluted with the water and mixed with constant stirring the acacia is precipitated in small masses. Neutral lead acetate does not gelatinize mucilage of acacia.

### 170.

The silver nitrate is entirely precipitated by the sodium chloride as silver chloride. It is customary to filter eye-washes, and if this one is filtered there will be only a very weak solution of sodium chloride and sodium nitrate left. There is no admissible method by which the precipitation can be prevented without changing the prescription.

### 171.

If concentrated solutions of the first two ingredients are mixed a reddish-brown salicylate of iron is precipitated. The citric acid in the syrup of lemon precipitates salicylic acid from a concentrated solution of lithium salicylate. By dissolving the iron salt in a part of the water and adding the syrup, then dissolving the salicylate in the balance of the water and mixing the solutions, a clear deep-red solution can be obtained. The deep-red color is due to the ferric salicylate formed.

### 172.

The calcium hypophosphite slowly reduces the mercuric chloride to mercurous chloride and finally to metallic mercury. This precipitation is not readily seen in the syrup of sarsaparilla, but if water is used instead of the syrup a turbidity is noticed as soon as solutions of the salts are brought together. The syrup of sarsaparilla also has a tendency to reduce the corrosive sublimate, but only very slowly.

### 173.

The maximum dose of *santonin*, as given by most authorities, is four grains, some giving as high as five grains. Hav-

ing two maximum doses coming so close together renders this prescription a dangerous one. Prescriptions containing santonin should be protected from the light, as light causes a change in color from white to yellow, probably with the formation of new compounds. Inquiry should be made to determine whether it is for a child or an adult and if for the former the prescription should not be filled, as two grains are said to have killed a child.

#### 174.

This mixture is far from being a solution. The benzoin and the Tolu are only partially soluble in alcohol and the acacia is insoluble. The insoluble matter quickly settles to the bottom of the mixture, forming a layer nearly equal in depth to that of the supernatant liquid. It, however, may be readily diffused through the liquid by agitation. A "Shake well" label is necessary.

#### 175.

A clear solution is formed at first, but in about a half hour needle-shaped crystals begin to fall. The precipitate increases for several hours and contains strychnine which is thrown out of solution with the iodide. Much commercial potassium iodide contains a carbonate, but in this case an iodide free from carbonate was used. It has been suggested to use acacia to suspend the precipitate, but it is objectionable if not dangerous to send out a shake mixture in which strychnine is precipitated.

#### 176.

Borax is alkaline in reaction and precipitates nearly all alkaloids from solutions of their salts. It precipitates the cocaine in this prescription, but the difficulty can be pre-

vented by the use of a little glycerin. The glycerin acts chemically on the borax, breaking it up and forming sodium metaborate and boric acid. (See No. 141.) If boric acid were used instead of borax no precipitation would occur.

### 177.

The acids were dissolved in the water and then the cocaine hydrochloride was added, getting a white precipitate at once. This is the borosalicylate of cocaine. If either acid is left out or if the amounts of both are reduced to one half the amounts, there will be little or no precipitation.

### 178.

When the sodium salicylate dissolved in a little water is added to the quinine sulphate dissolved in the balance of the water with the aid of the hydrobromic acid, a curdy sticky precipitate is formed that cannot be mixed with the liquid. Two chemical reactions take place. Sodium salicylate with quinine sulphate forms sodium sulphate and the nearly insoluble quinine salicylate. Hydrobromic acid with sodium salicylate forms sodium bromide and the nearly insoluble salicylic acid. Permission to use alcohol or some other solvent should be obtained.

### 179.

On mixing solutions of the first two ingredients a reaction takes place, with the formation of free iodine and a reddish-brown precipitate. The aqueous solution of iron and quinine citrate is acid, and ferric salts in acid solutions with potassium iodide are reduced to ferrous compounds, iodine being liberated. Iodine in an aqueous solution of potassium iodide is a general alkaloidal reagent and precipitates the

quinine. Neutralizing the solution will prevent liberation of iodine for a time.

180.

This prescription is frequently given as an example of the incompatibility of bromides with strychnine salts. It is said that crystals of strychnine bromide will form after the mixture has been standing for a half hour. The writer failed repeatedly to get a precipitate even on making the solution twice as strong as that called for and also varying the proportions. The precipitation is partially explained by some writers by saying that the strychnine bromide is soluble in water, but insoluble in a solution of potassium bromide. In many instances the commercial potassium bromide is alkaline, due to the presence of a carbonate which has been left in to aid the preservation of the bromide. The carbonate precipitates the strychnine as the free alkaloid.

181.

Although the Fowler's solution is alkaline, there is enough of acid in the prescription to prevent any precipitation by it. The insoluble ferric phosphate or hypophosphite is thrown down. By using the tincture of citro-chloride of iron no precipitation results at once, but does after a day or two. If it were admissible to use twice as much phosphoric acid as tincture of iron there would be no precipitation.

182.

It is a somewhat disputed question whether in such a prescription there would be any mercuric chloride formed, and if so whether the amount formed would be sufficient to have any disagreeable physiological effect. If the prescription is to be used up in a short time probably no bad results would follow. [See HYDRARGYRI CHLORIDUM MITE, No. 7.]

**183.**

Terpin hydrate dissolves in about 250 parts of water and iodol in about 5000 parts of water. These should be finely powdered before mixing with the other ingredients, and the prescription dispensed with a "Shake well" label. The glycerin and syrup are sufficiently viscid to keep the insoluble substances in suspension for a time.

**184.**

Each ingredient should be powdered separately and then mixed lightly with the other. If the two are rubbed together with some force slight crackling explosions take place. A sharp blow would probably cause serious results. The patient should be cautioned. With a little care on the part of the pharmacist and patient no ill results will follow from this combination.

**185.**

In this mixture the menthol floats on top and the boric acid goes to the bottom. Using alcohol, glycerin, or a fixed oil instead of water will not make a clear solution. The attention of the physician should be called to this prescription.

**186.**

Santonin is soluble in about 40 parts of alcohol, nearly insoluble in water, and not readily soluble in turpentine. The amount prescribed is not all soluble in the mixture. The turpentine does not mix, but floats on top. Extractive matter from the fluid extracts is precipitated. The santonin should be in the form of a fine powder and the mixture made into an emulsion.

## 187.

The potassium carbonate is deliquescent. It should be powdered with some absorbent powder, such as althæa, and then the arsenic, previously triturated with some sugar of milk, added. Next add the mass of iron and if necessary a little water. The pills should be dispensed in a bottle protected from the atmosphere; otherwise they will become soft.

## 188.

This solution has a much larger proportion of active ingredients than is usually prescribed in an eye-wash. Probably the prescriber meant grains instead of drams. It should not be dispensed without consulting the physician, as it would cause intense irritation. In case the prescriber cannot be reached and it seems urgent that the prescription should be filled the quantities can be reduced to grains and the prescriber notified **at** the earliest opportunity.

## 189.

Mixing a solution of silver nitrate with a solution of cocaine hydrochloride produces a white precipitate of silver chloride. If this is filtered out about one half of the silver is removed. The pharmacist should use cocaine nitrate. If he does not have it he can make it by dissolving the one grain of cocaine hydrochloride in a little water and adding one half a grain of silver nitrate in a little water. This makes cocaine nitrate and silver chloride. The precipitate can then be filtered out and the requisite amount of silver nitrate added.

## 190.

Borax is soluble in 16 parts of water, and in this case there is not enough to dissolve it. Boric acid requires 18

parts of water to dissolve it, but it is much more soluble in a solution of borax. The principal difficulty with this prescription is that the mucilage of acacia is gelatinized by the borax, making a stiff mass. Boric acid has not the effect of gelatinizing acacia, and borax is prevented from doing so by the presence of sugar. Glycerin also prevents this action by decomposing the borax.

### 191.

The first two ingredients are both disinfectants and oxidizing agents, yet they react on each other, with the reduction of both. The chemical reaction is represented by the following equation:

The acid necessary for the reaction is usually present in the hydrogen dioxide water, as a small amount is allowed to remain for preservation of the dioxide. The amount of hydrogen dioxide which 20 grains of potassium permanganate would act upon is 10.7 grains. If the dioxide water is official 1 fluid ounce contains about 13.7 grains of hydrogen dioxide, which would be sufficient to reduce all of the permanganate. Usually there will be a precipitate of manganese dioxide, there not being enough of acid to convert all into a salt. By adding a grain or two of sodium bicarbonate to neutralize the acid some of the change can be prevented. The directions are: Let them be mixed by vigorous shaking. Label: Let it be applied to the affected parts night and morning.

### 192.

The cherry-laurel water of the Br. P. contains 0.1 per cent. of hydrocyanic acid. It has been proved that calomel with hydrocyanic acid is changed to mercuric chloride, mercuric cyanide, and metallic mercury. Hydrocyanic acid displaces

hydrochloric acid in dilute solutions, while in concentrated solutions hydrochloric acid displaces hydrocyanic acid. There is such a small amount of hydrocyanic acid that there would not be much of the mercuric salts formed.

193.

A mixture of thymol, alcohol, and ammonia is colorless at first, but acquires a decided though not deep green color on standing for a week. If the chlorinated soda solution is added to a mixture of thymol, alcohol, and ammonia a light-green clear solution is formed at once. Within ten minutes this becomes slightly turbid and of a deep-green color. On allowing it to stand a day an oily fluid separates from the dark-green solution in little round globules. These globules are black in appearance, but when broken up into very small ones they are blue-red or purple in color. This oily liquid has nearly the same specific gravity as the aqueous liquid.

194.

When the cocaine is mixed with the solution of silver nitrate it gives a black precipitate of silver oxide. If the cocaine is first dissolved in water with the aid of a little dilute nitric acid, which converts the alkaloid into a salt, the solution can be mixed with the silver nitrate without any precipitation. A better method of filling would be to use the cocaine hydrochloride and follow the directions under No. 189.

195.

This mixture gives at first a clear solution, but within a few minutes it begins to grow turbid from the production of a light-brown precipitate, which quite rapidly increases and becomes dark brown. This precipitation is due chiefly to the action of the eugenol in the pimenta on the tincture of iron. This is somewhat characteristic of all phenols, and

the color varies with the dilution. If the tincture of iron is not so very acid the quinine may precipitate some of the iron.

**196.**

The quinine sulphate dissolves in the water and citric acid, making a clear solution that does not precipitate on standing. On adding the potassium citrate, crystals begin to separate at once. Adding more citric acid will dissolve the precipitate and the addition of another portion of potassium citrate causes a precipitation again. It is said that quinine acid citrate is formed. Whatever the precipitate is, it is probably thrown out of solution by making a concentrated solution of potassium citrate, although this does not entirely explain the result since acid clears up the mixture again. The directions are: Mix. Label: A dessertspoonful after meals.

**197.**

In the presence of moisture this mixture becomes black. The pilocarpine hydrochloride probably breaks up the calomel, forming mercuric chloride which combines with the alkaloidal salt, and metallic mercury which gives the mixture its dark color. Several of the alkaloids have that property. The directions translated into English are: Mix. Send 8 such powders. Label: Of these powders take one night and morning.

**198.**

There is considerable danger in mixing these ingredients and the directions to "mix cautiously" should be followed. The potassium bichromate was powdered and mixed with the tar. To this the sulphuric acid was added with constant stirring. Heat and acrid fumes were generated. The mixture was a black, soft, granular mass, which after standing a day was scarcely acid to litmus paper. It probably had but little caustic effect.

## 199.

Sometimes the lime liniment causes a darkening when mixed with citrine ointment. In making the citrine ointment, if the nitric acid be insufficient in amount or the temperature rise too high, the oxidation of the fatty matter is effected in part at the expense of the mercuric nitrate, forming a mercurous nitrate. The calcium hydroxide in the lime liniment acts on the mercurous salt, forming the black mercurous oxide. A translation of the directions is: "Make an ointment, to be used as directed."

## 200.

When chloral hydrate and antipyrine are brought together in concentrated solutions in the right proportions an oily liquid separates and upon standing forms crystals of monochloral antipyrine, commonly known as hypnal. In this case there is more than enough of chloral for the antipyrine, the proper proportions being 47 Gm. of chloral to 53 Gm. of antipyrine. Possibly there may be some dichloral antipyrine formed in this prescription. At least there is a separation of an oily liquid that does not solidify. The resinous matter in the fluidextracts is precipitated by the water. The prescription should not be dispensed without consulting the prescriber.

## 201.

Ferric acetate is formed in this prescription and it gives a very deep red color to the solution. If the ingredients answer the pharmacopœial requirements there will be no incompatibility. However, the solution of ammonium acetate is sometimes quite strongly alkaline, due to excess of ammonium carbonate or deficiency of acetic acid used; and if the tincture of iron is free from an excess of acid the alkali causes the formation of ferric hydroxide which will be kept in solution by the syrup.

**202.**

As this prescription is written it would make a dangerous mixture. The solution of potassium arsenite, being alkaline, slowly precipitates the strychnine. If the solution of arsenous acid were directed instead of Fowler's solution there would be no danger and the physiological effect would be the same. The Fowler's solution should be neutralized before using.

**203.**

When the first two ingredients are rubbed together in a mortar chemical reaction takes place with enough violence to amount almost to an explosion, and there is an evolution of a large volume of white fumes. If the two chemicals are powdered separately and then mixed together lightly the change is slower and the mixture gradually turns brown. If mixed with separate portions of the cerate and then these mixed the reaction is retarded, but the ointment ultimately becomes brown. Chloral hydrate and potassium cyanide form dichloro-acetic acid, and in concentrated solutions form a crystalline compound which is not very soluble in water (M. & M., II. 4).

**204.**

The quinine sulphate would not be entirely soluble even though there were no tannic acid in the infusion. The tannic acid converts the quinine sulphate into the less soluble quinine tannate. The oil in the spirit of rosemary is thrown out of solution, as well as some of the inert matter in the tincture. This is a poor combination, even for an external preparation.

**205.**

By triturating the zinc oxide and carbonate with the petrolatum, and then adding the lime water gradually, a

partial emulsion can be effected. By the addition of thirty grains of acacia an emulsion can be made, which soon separates into three layers, the bottom consisting of the zinc salts, the middle chiefly of water, and the top of the emulsified petrolatum. These are readily mixed on agitation. Petrolatum is not saponified or otherwise chemically acted upon by calcium hydroxide or other hydroxides, as are the organic fixed oils and fatty substances. The best way to fill this prescription is to replace about one half of the petrolatum with anhydrous wool-fat, mix the water with this, then the oxide and carbonate, and lastly the petrolatum.

### 206.

Salicylic acid is soluble in 308 parts of water and 60 parts of glycerin; consequently a solution cannot be made unless something else be added. "With half its weight of borax and two and a half times its weight of glycerin a twenty-five per cent. solution of salicylic acid may be obtained." (N. S. D., 76.) This prescription with thirty grains of borax would make a clear solution. But the addition of borax, potassium nitrate, ammonium citrate, or sodium phosphate should not be made without the knowledge of the prescriber. In the absence of the physician this should be dispensed as a "Shake" mixture.

### 207.

By mixing these ingredients a bright-red precipitate is formed in a few minutes and the iodine color of the liquid is nearly destroyed. In the course of a day or two there is no free iodine present. Probably three chemical reactions take place. The mercurous chloride and potassium iodide in the tincture form potassium mercuric iodide, potassium chloride, and metallic mercury. The metallic mercury with the iodine forms mercurous iodide, and this with more iodine makes

the red mercuric iodide. The final products depend to some extent upon the proportion of the tincture to the calomel.

### 208.

The trouble with this prescription is to get into and to keep in solution the two alkaloidal salts. Cocaine hydrochloride is soluble in .4 parts of water, 2.6 parts of alcohol, 2800 parts of ether, or 18.5 parts of chloroform. Morphine sulphate is soluble in 15.3 parts of water, 465 parts of alcohol, and nearly insoluble in ether or chloroform. The alcohol in the tincture is not present in sufficient amount to dissolve all of the morphine sulphate, and the ether and chloroform would throw out about all that the alcohol dissolves. As a rule, the free alkaloids are much more soluble in ether or chloroform than are their salts, but morphine is an exception. Morphine dissolves in 168 parts of alcohol (not enough in the two ounces of the tincture to dissolve the amount that would correspond to 15 grains of the sulphate), in 4464 parts of ether, or 1800 parts of chloroform. It is impossible to get the morphine sulphate or the free alkaloid into solution. The prescription should not be dispensed.

### 209.

In neutralizing tincture of ferric chloride by adding ammonia water to it a precipitate is formed, consisting of ferric hydroxide and basic ferric chloride. If the ammonia water is added to a part of the syrup, and then this added to the tincture of iron previously diluted with the balance of the syrup, no precipitation will occur even though an excess of ammonia is used. The resulting fluid is of a very dark red color. The syrup acts as a solvent for the ferric hydroxide. It is better to add a strong solution of ammonia than a weak one, as the water dilutes the syrup so much that it may not prevent the precipitation.

## 210.

This makes at first a clear colorless solution, but within a day or two becomes of a dark brownish-red color. On standing a few days there is a slight precipitation, the amount depending on the condition of the salt and the spirit. If the salt is neutral and the spirit strongly acid a small amount of salicylic acid will be thrown out of solution. By neutralizing the acid the precipitation is prevented and the coloration hindered, although care must be used not to make the solution alkaline, as an alkaline solution of a salicylate quite quickly becomes colored. Possibly there is some nitrosalicylic acid formed in this prescription. The directions are: Mix. Label: Dessertspoonful three times a day.

## 211.

On adding the sulphurous acid to the tincture of iron the mixture becomes of a much darker red color at first and then nearly colorless. The glycerin may now be added and then the potassium chlorate dissolved in the water. There is barely a sufficient amount of water to dissolve the chlorate at the ordinary temperature, and after mixing with the other ingredients some of the salt is thrown out of solution by the alcohol of the tincture. Different chemical reactions take place, depending on the order of mixing. The possible reactions are as follows: 1. Between the ferric iron and the sulphurous acid, forming ferrous sulphate and hydrochloric acid. 2. Between the potassium chlorate and the hydrochloric acid in the tincture, forming chlorine. 3. Between the chlorine and the ferrous sulphate, forming a ferric salt and a chloride. 4. Between the chlorine and the sulphurous acid, forming sulphuric and hydrochloric acids. 5. Between the chlorine and the glycerin. 6. Between the potassium chlorate and the sulphurous acid, forming potassium sulphate and hydrochloric acid.

**212.**

This prescription was filled by dissolving the inorganic salts in the water and the camphor in the alcohol. The tincture was added to the alcoholic solution and then the two solutions mixed. A turbidity resulted at once, and on standing for some time crystals were formed. This is due to the insolubility of the inorganic salts in the alcohol, which throws them out of their aqueous solution.

**213.**

There is not enough of water to dissolve the borax, it being soluble in 20.4 parts of water. Mercuric chloride requires about 13 parts of water, and the twenty grains would require about one half of an ounce. If the mercuric chloride is dissolved in part of the water, and the borax is mixed with the balance of the water and then with the corrosive sublimate solution, or if the borax is mixed with the water and then the mercuric chloride added to this, the result will be about the same. In either case there will be formed a dark reddish-brown precipitate of an oxychloride of mercury, and also a white precipitate of borax. The mercury is ultimately entirely precipitated. If heat is used in dissolving the borax there are quite large clear crystals formed on standing, probably borax. The directions are: Make a lotion. Use frequently.

**214.**

The carbonate in the Fowler's solution precipitates the ferrous carbonate, which is white if purely ferrous, but quickly oxidizes, changing to a dark green. This slowly oxidizes still more, forming a red-brown basic ferric salt. Probably some of the arsenic is also precipitated. The sugar in the syrup tends to prevent the oxidation of the ferrous carbonate. Fowler's solution should first be neutralized with dilute sulphuric or hydrochloric acid.

**215.**

Piperazine is so deliquescent that it becomes liquefied when exposed to air; consequently it cannot well be dispensed in the form of powders. It also absorbs carbon dioxide from the air. It should be dispensed in solution. The directions are: Let it be triturated well. Let 12 powders be made.

**216.**

The cocaine hydrochloride is best dissolved in a little water before mixing with the base. No difficulty is experienced in filling this prescription, but the use of a metallic spatula must be avoided on account of the coloration with gallic acid.

**217.**

Crystallized carbolic acid when triturated with lead acetate or with thymol gives a liquid, and the reaction cannot be prevented by first mixing the ingredients with separate portions of the base and then rubbing these together. Either phenol or thymol soften the oil when rubbed with it. The mass is too soft to make into suppositories, and it is necessary to use some drying-powder or spermaceti to stiffen it. The directions are: Mix carefully. Make 10 suppositories.

**218.**

Three chemical reactions may take place in mixing these ingredients. One is between the sodium benzoate and the sulphuric acid, forming sodium sulphate and benzoic acid. The benzoic acid is only sparingly soluble in water, but there is enough of alcohol in the elixir to keep it in solution. Another reaction is between the sulphuric acid and the quinine sulphate, making the soluble bisulphate. The third reaction is between the sodium benzoate and the quinine salt, forming quinine benzoate, which is not very soluble in water. The prescription was filled by dissolving the quinine sulphate

in part of the elixir and the benzoate in the remainder and then mixing the solutions. Precipitation commenced almost at once and in a short time there was a solid mass of needle-shaped crystals. This could be shaken up so that it could be poured.

### 219.

The quinine sulphate was dissolved in the tincture of iron with the hydrobromic acid and then an aqueous solution of the corrosive sublimate added. A precipitation commenced at once and continued for some time. Mercuric chloride is a general alkaloidal reagent, and so also is the double compound that it forms with the hydrobromic acid; these combine with the quinine to form insoluble compounds. In such a prescription as this the danger lies, not in the precipitation of the quinine, but of the mercuric chloride, and in this particular instance it is almost entirely thrown out of solution. This prescription might be considered dangerous to dispense.

### 220.

The potassium nitrate and the lead acetate were powdered separately and then mixed with the oil. To this the sulphuric acid was added slowly with constant stirring, avoiding letting the mixture get hot. The carbolic acid was added last. The mixture thus produced was black and thick. Several reactions ensue, depending to some extent upon the order of mixing. 1. Sulphuric acid with lead acetate gives lead sulphate and acetic acid. 2. Sulphuric acid with potassium nitrate forms potassium sulphate and nitric acid. 3. The nitric acid may act on the oil, oxidizing it. 4. The nitric acid may act upon the carbolic acid, forming picric acid. 5. The sulphuric acid forms with carbolic acid sulphocarbollic acid. 6. Sulphuric acid has a carbonizing effect upon the oil.

**221.**

No matter what order is used in mixing these ingredients a clear solution cannot be obtained. Several chemical reactions are liable to take place. 1. Potassium acetate with tincture chloride of iron gives a red solution of ferric acetate. 2. Potassium acetate with a solution of quinine sulphate gives the almost insoluble quinine acetate. 3. Sodium bicarbonate precipitates morphine from a solution of its salt. 4. Sodium bicarbonate precipitates ferric hydroxide from the tincture of iron. 5. Sodium bicarbonate precipitates the quinine from a solution of the sulphate. 6. The morphine sulphate gives a blue-green solution with the tincture of iron. By replacing one half of the water with glycerin the precipitation can be prevented to some extent.

**222.**

The strychnine and the iodoform are insoluble in the syrups. The strychnine sulphate should be used instead of the alkaloid and then it will dissolve in the syrups. The iodoform should be finely powdered before mixing with the other ingredients and a "Shake" label should be put on the bottle. Very frequently syrup of hydriodic acid contains some free iodine, which would precipitate the alkaloids, but by mixing the two syrups first the iodine is reduced by the hypophosphorous acid in the syrup of hypophosphites. There is perhaps a little danger of the hydriodic acid precipitating the strychnine, as under certain conditions iodides precipitate that alkaloid.

**223.**

On adding a part of the glycerin to the balsam a nearly solid mass results which is thinned some by the balance of the glycerin so that it will run slowly. There may be some chemical reaction, but more probably the thickening is due to the separation of part of the resinous matter. On standing

exposed to the air the glycerin absorbs moisture and the mixture becomes thinner, the balsam coming to the top. The odor of the iodoform is destroyed, the balsam combining with the iodoform (U. S. D., 662).

#### 224.

The vaselin will not dissolve in the bay rum and on being melted and shaken with the bay rum until cold separates in a mass. Acacia cannot be used to emulsify it on account of the alcohol present. The addition of soap or resinous matter in admissible amounts does not help it. If lanolin is used instead of petrolatum the acid can be mixed with it and about one half of the alcohol, making a homogeneous mass, but the balance of the alcohol separates. The amount of carbolic acid is very large, the mixture being so strong as to quickly make the skin white. The prescriber should be consulted.

#### 225.

An oily liquid separates. Antipyrine with phenol, antipyrine with chloral hydrate, or phenol with chloral hydrate gives a liquid insoluble in water. Borax acting on chloral hydrate gives chloroform.

#### 226.

Exalgine triturated with camphor makes a damp powder, or with salol it gives a liquid. Salol and camphor triturated together give a liquid. This mixture cannot be dispensed in the form of powders unless a large amount of some absorbing-powder, as slippery elm, is used. Perhaps the best way to dispense this combination would be to get the prescriber's consent to make an emulsion with water and acacia, using some expressed oil of almond to aid the emulsification.

**227.**

Ichthyol when rubbed with ammonium chloride makes a mass resembling a pill mass and gas is slowly evolved, the mixture remaining neutral to litmus. On adding the phenol, the mass softens and mixes readily with the wool-fat. Crystallized phenol when rubbed with ichthyol makes it thinner. This should be filled by mixing the ammonium chloride with wool-fat, then adding phenol and lastly the ichthyol.

**228.**

On mixing these two ingredients a white precipitate of calcium carbonate is formed, the spirit containing ammonium carbonate. The lime water also throws out of solution the oils of the aromatic spirit. Ordinarily the precipitate would not be filtered out but the mixture dispensed with a "Shake well" label.

**229.**

The bismuth subnitrate is not dissolved. The aromatic spirit of ammonia precipitates the zinc as zinc carbonate, due to the presence of ammonium carbonate. The carbonate may be slowly decomposed by the bismuth subnitrate, liberating carbon dioxide, which might burst the bottle if tightly corked. Syrup is sufficiently viscid to keep the insoluble matter in suspension while pouring out a dose. A "Shake well" label is necessary.

**230.**

Ergotin does not mix well with alcohol and should be rubbed up with a little water first and then triturated thoroughly with the tincture. The mixture is not clear at best.

**231.**

Reaction takes place between the two chemicals, resulting in the formation of the soluble ammonium acetate and the precipitation of a white basic carbonate of lead, which is really a carbonate and hydroxide combined in various proportions. All the lead is precipitated. As it is for external use, it may be dispensed.

**232.**

This prescription would make pills weighing nearly eight grains each even though no excipient is used, and as two of the ingredients are liquids, it would require a large amount of an absorbent powder to make a mass and the pills would be entirely too large. A smaller amount of excipient can be used, and at the same time a larger amount of medicinal matter can be taken, in the form of capsules than in a pill. This prescription should either be put into capsules or be made into two or three times as many pills as directed, of course increasing the number to be taken at a dose.

**233.**

Several chemical reactions take place, depending on the order of mixing. The quinine sulphate is not all dissolved by the elixir. 1. The sodium salicylate combines with the quinine salt, forming the nearly insoluble quinine salicylate. 2. The quinine sulphate forms with the mercuric chloride a double compound which is insoluble in water but soluble in alcohol. In this particular instance there is not enough of alcohol in the elixir to dissolve it. 3. The quinine is also

precipitated as the free alkaloid by the alkali in Fowler's solution. 4. An alkaline solution of potassium arsenite reduces mercuric chloride to calomel, but in this prescription there is not enough to make any trouble. In filling this, quite a bulky precipitate results.

### 234.

The U. S. Dispensatory (19th ed., 644) gives a formula for making the colorless hydrastis, which consists of twenty grains of hydrastine hydrochloride or sulphate dissolved in a pint of a mixture of glycerin and water. In this prescription we have the borax decomposed by either the honey or the glycerin, forming boric acid and sodium metaborate. The boric acid liberates carbon dioxide from the sodium bicarbonate. Carbon dioxide may also be liberated by the bismuth subnitrate, bismuth subcarbonate being slowly formed. The bicarbonate of sodium may also liberate the hydrastine from the acid with which it is combined, but the alkaloid will not be precipitated in the presence of so much honey, glycerin, and water.

### 235.

The compound liniment of camphor contains ammonia, and this with the iodine forms ammonium iodide and a little ammonium iodate. The mixture at first is red brown, but becomes colorless as the iodine is changed. There is some danger of forming the explosive iodide of nitrogen. [See under IODUM.]

### 236.

This mixture quickly becomes blue, the color gradually deepening, and a turbidity is produced. The addition of an acid turns it red. Mention is made of this change in Allen's

Organic Analysis (vol. II. p. 539), and also in Muir and Morley's edition of Watts' Dictionary (vol. III. p. 832), but no explanation is given nor intimation of the chemical change which takes place.

**237.**

The trouble in filling this prescription comes in getting the extracts into solution. The best way is to make a very strong aqueous solution of the chloral hydrate and this will dissolve the extracts; to this solution add the alcohol and then the water containing the bromide, the latter solution to be added slowly with constant stirring. Some precipitate will form but it can be readily diffused through the liquid by agitation. Using another ounce of alcohol makes a better solution.

**238.**

In Scoville's Art of Compounding the statement is made that sodium bicarbonate with calomel forms corrosive sublimate slowly, the change not taking place within four to six weeks ordinarily, so that, except under unusual conditions, any prescription would be used before mercuric chloride is formed. It is a very common practice of physicians to direct the use of these two chemicals together and no ill effect seems to have resulted.

**239.**

Sodium bicarbonate requires 12 parts of water for solution. While there is sufficient water to dissolve the two salts and the acid, a precipitate very slowly forms after the addition of the chloroform, due, probably, to the throwing out of solution some of the bicarbonate by the chloroform. The chloroform is not all dissolved, but sinks to the bottom. In dissolving sodium bicarbonate in water heat should not be used, because carbon dioxide is liberated, forming the normal

sodium carbonate. Carbolic acid does not liberate carbon dioxide from the sodium bicarbonate.

#### 240.

When antipyrine is rubbed with resorcin a pasty mass results, and this gradually becomes liquid. Acetanilide and resorcin triturated together make a liquid. When an aqueous solution of antipyrine is mixed with a solution of resorcin a white precipitate is formed. Acetanilide requires 179 parts of water for solution, so that in this prescription it will not be all dissolved. No matter how this is filled a clear solution cannot be made. Acacia or some other suspending agent should be used.

#### 241.

Cocaine hydrochloride is soluble in 2800 parts of ether or 2.6 parts of alcohol. As collodion is made up of 3 volumes of ether to 1 of alcohol, this salt will not dissolve in it. The free alkaloid cocaine is readily soluble in alcohol or ether, and consequently in collodion and this should be used.

#### 242.

Atropine sulphate is nearly insoluble in fixed oils. The free alkaloid is soluble in 38 parts of olive oil, and this is what should be used in filling this prescription. The physician should be notified of the change.

#### 243.

The chromic acid and cocaine hydrochloride were dissolved in separate portions of water, using one dram for each, and these solutions were mixed. A heavy yellow sticky precipitate formed which made a mass. It is necessary to use about twelve drams of water to get a clear solution and then it may precipitate on standing for a time. Alcohol or glycerin

cannot be used with chromic acid. It cannot well be dispensed as written.

**244.**

The spirit of nitrous ether gives a blue color with a fresh tincture of guaiac but a brown one with a tincture that has been exposed to the light for a time. The nitrous acid would probably affect the alkaloid colchicine, since it is so easily decomposed. Acids usually give yellow solutions with colchicine, but this change would not be noticed here. The syrup precipitates resinous matter from the tinctures.

**245.**

The potassium sulphide in the "liver of sulphur" precipitates part of the zinc as the white zinc sulphide. There is left in solution some zinc sulphate, potassium sulphate, and potassium thiosulphate.

**246.**

The aromatic sulphuric acid was probably added to reduce the bulk of the quinine, but an incompatibility is thereby introduced. The acid will liberate the carbon dioxide from the mass of carbonate of iron, causing the pills to swell and forming ferrous sulphate. The acid should be omitted.

**247.**

There will be a little silver permanganate thrown out of solution, it being soluble in 109 parts of water. This salt, like other silver salts, is decomposed by light and also by heat.

**248.**

Thymol and menthol liquefy when triturated together. If a powder were used to mass the liquid the required cap-

sule would be entirely too large to swallow. By putting in the menthol, then the guaiacol carbonate, then the thymol, and lastly the eucalyptol, a kind of mass will be formed, but it will be necessary to seal the capsules.

#### 249.

Benzoic acid is soluble in 281 parts of water and salicylic acid in 308 parts of water. If the directions to make a solution with the aid of heat are followed the acids on cooling will separate out in much larger crystals than at first. A better mixture will be obtained by rubbing the acids well in the mortar and then mixing with the water and cocaine salt in the cold. The acids do not precipitate the alkaloid.

#### 250.

The pharmacist in filling this prescription shook the two salts with the water, expecting to get a clear solution, but instead got quite a heavy precipitate. Some samples of zinc iodide do not entirely dissolve in water and when filtered give a precipitate with a solution of zinc chloride. This is due to an alkali being left in to preserve the iodide. Some samples of zinc chloride do not entirely dissolve on account of the formation of some oxychloride resulting from too high fusion.

#### 251.

The oil, chloroform, spirit of camphor, and aromatic spirit of ammonia mixed make a clear solution, but on the addition of the tincture and the whiskey the oil and chloroform are thrown out of the solution, and on standing the mixture separates into two clear layers the lower one being chloroform and oil. There is no danger of the morphine being precipitated, for, although the free alkaloid is formed by the ammonia, there is enough of alcohol and chloroform to keep it in solution.

**252.**

The carbonate in the solution of potassium arsenite precipitates the yellow-white silver carbonate. The arsenic also combines with the silver, forming yellow silver arsenite, which is insoluble in a neutral aqueous liquid. In this prescription the silver is not all precipitated. The yellow-white precipitate becomes dark on standing for a day, with the formation of silver oxide or metallic silver or both. By slightly acidifying Fowler's solution with nitric acid, precipitation can be prevented.

**253.**

This mixture on standing separates into two layers, the oil coming to the top. Part of the iodine combines with the oil, but not all. Probably some other oil, less offensive than cod liver, might have been used by the physician with equal advantage.

**254.**

Castor oil and nearly all other fixed oils do not make clear solutions with glycerin. A "Shake well" label is necessary for this prescription. The oil need not be emulsified, as the two liquids are thick and do not separate quickly.

**255.**

On dissolving the quinine bisulphate in glycerin, alcohol, and part of the water and the resorcin in the balance of the water, a clear solution is obtained. In a few minutes small needle-shaped crystals are formed and crystallization continues for some time. The resorcin destroys the fluorescence and precipitates the quinine.

**256.**

Salicylic acid and resorcin dissolve in the collodion. Chrysarobin only partially dissolves and is difficult to mix with collo-

dion after standing in the bottle for a time. It requires 114 parts of ether and 308 parts of alcohol for solution.

257.

The antipyrine was dissolved in the syrup and added to the syrup of iodide of iron without producing any apparent change at first. After a day or two, however, the liquid became dark red and a crystalline precipitate of a deep-red color began to form. These crystals grew as the liquid was allowed to stand. Their composition was undetermined.

258.

Potassium permanganate oxidizes carbolic acid to oxalic acid and carbon dioxide. (Morley and Muir, 111. 832.) The permanganate is reduced and precipitated as manganese dioxide, which makes the mixture a semi-solid, but by shaking it may be gotten into a condition so that it can be poured. There is a large excess of carbolic acid not oxidized.

259.

If a solution of borax is added to a solution of lead acetate a white precipitate of lead borate is formed. Or if the glycerin is added to the solution of lead acetate and then the borax solution added a precipitate is also formed. But if the glycerin is added to the borax solution first the borax is decomposed, with the ultimate formation of sodium metaborate and boric acid, making an acid solution which does not precipitate the lead.

260.

The iodine is reduced by the tannic acid, but not completely, and a turbid mixture is made. According to the U. S. Dispensatory (p. 81), hydriodic acid is formed and combines with a portion of the tannic acid and remains in solution,

while the oxygen of the decomposed water combines with another portion of the tannic acid to form an insoluble compound. This mixture is capable of dissolving iodine.

**261.**

If the potassium chlorate and the glycerin are rubbed together an explosion is liable to occur. The chlorate and acid react to form a chloride and sulphate. After a day or two no odor of sulphurous acid can be detected. The chlorate does not all dissolve in the water, but the excess should not be filtered out, as it is to be mixed with more water before being used.

**262.**

Chromic acid oxidizes glycerin to oxalic and carbonic acids; it oxidizes alcohol to aldehyde and acetic acid. There is great danger of causing an explosion or igniting the organic matter in filling this prescription. The reaction is very violent. The chromic acid is changed to an insoluble oxide of chromium. The prescription should not be filled.

**263.**

The National Dispensatory (p. 788) states that when the first two ingredients are rubbed together explosion takes place, due to the formation of iodide of nitrogen. By mixing the first two ingredients with separate portions of lard and then mixing these there is but little danger. The iodine is reduced and the ointment becomes nearly white.

**264.**

When the salol is added to the tincture of iron a dark-green to red mixture is produced. The salol is partially dissolved, but is nearly all precipitated when the syrup is added. With a dilute solution of iron an alcoholic solution of salol gives a violet color.

## 265.

The tincture of iodine and the collodion mix without any trouble or any reduction of the iodine even on standing for several days. But when the ammonia water is added and thoroughly shaken with the mixture it coagulates the collodion, if the tincture of the 1890 Pharmacopœia is used, but not if the present official tincture is used. This coagulum dissolves in a day or two. The difference between the two tinctures is that the present official one contains potassium iodide. The resolution of the coagulum when the 1890 tincture was used is probably due to the formation of ammonium iodide. The ammonia changes the iodine to ammonium iodide chiefly and a small amount of ammonium iodate. When there is a deficient amount of ammonia some explosive iodide of nitrogen is liable to be formed. This prescription becomes nearly or entirely colorless in a few days.

Sometimes equal volumes of tincture of iodine, collodion, and stronger ammonia water are prescribed. In this case some coagulum is formed but dissolves in a few hours and the solution becomes yellow by the next day. The coagulum is the gun-cotton thrown out of solution.

## 266.

Shaking the solution of potassium hydroxide with the olive oil gives a white emulsion; some soap is formed in the reaction and this acts as an emulsifying agent. The compound iodine solution added to this gives a red-brown mixture, which slowly loses its color, becoming white within a few hours. The iodine is partly changed by the alkali, forming an iodide and an iodate. Part of the iodine combines with the oil to form a nearly colorless compound in which two atoms of the iodine are combined with one molecule of oleic acid.

## 267.

This mixture makes a clear solution at first, but soon commences to become turbid and give a slight deposit. This is

due to the action of the ferric chloride on the cinnamic aldehyde in the oil of cinnamon which is in the water. The arsenic and quinine are not precipitated.

**268.**

This ointment, which is nearly white at first, soon becomes darkened and ultimately nearly black. The pyrogallie acid is oxidized and turned black by contact with air and light. It is also oxidized by the mercuric chloride, which is reduced to metallic mercury, while the pyrogallie acid is changed to acetic and oxalic acids (Richter, 695).

**269.**

When the first two ingredients are rubbed together a liquid is produced, and this mixed with the lard makes a very thin ointment in warm weather. The prescription was filled by replacing one half the lard by that amount of simple cerate. Rubbing the ingredients with separate portions of lard and then these together seems not to prevent the reaction between the exalgin and naphthol.

**270.**

This makes a clear prescription at first, but on standing a precipitate begins to form in a few hours and continues for some time. The appearance of the precipitate is that of iron pyrophosphate. It has been suggested that potassium acetate salts out the iron pyrophosphate. Precipitation can be prevented by making the elixir slightly alkaline with ammonia.

**271.**

On adding a solution of pyrogallol to a solution of lead acetate a white precipitate is formed, which turns dark in a few days, the upper portion getting black much sooner than the lower. The lead in this prescription is not all precipitated.

## 272.

If the oil is emulsified and then the borax dissolved in the water is added a tough solid mass is formed. If, however, the borax is dissolved in the syrup with a little water and then added to the emulsion no trouble is experienced. Sugar prevents the gelatinizing effect of borax on the acacia.

## 273.

This prescription was filled by dissolving the salts in separate portions of water and then mixing. After a few hours a crystalline precipitate began to appear. The strychnine was liberated from the sulphate by the cyanide solution, which was alkaline. Potassium cyanide is generally more or less alkaline, depending upon its exposure to air. The carbon dioxide of the air decomposes it, liberating hydrocyanic acid. After neutralizing the potassium cyanide with sulphuric acid no precipitation resulted.

## 274.

While these ingredients make a homogeneous mixture, on allowing it to stand the glycerin separates out. By using three fourths of a dram of lanolin in place of that much of the ointment, and rubbing with it the glycerin and borax and then the ointment, an excellent mass is formed, from which the glycerin does not separate.

## 275.

The two salts were dissolved in separate portions of the syrup and then mixed. A turbidity resulted, and on filtering out the white precipitate and adding ammonia to it it was darkened, indicating calomel. The tartar emetic reduces the mercuric chloride to mercurous chloride.

**276.**

Codeine is strongly basic and liberates ammonia from a solution of ammonium chloride. This can be readily proved by suspending wet red litmus paper in the bottle over the liquid. Codeine also liberates morphine from its salt, so that in the presence of the ammonia which is formed in this prescription there is some danger of the morphine being precipitated. A slight precipitate makes its appearance after some hours and gradually increases, but the morphine is not nearly all thrown out of solution. A salt of codeine, as the sulphate, should be used.

**277.**

When lime and sulphur are boiled together a red solution is formed. The calcium and sulphur unite to form calcium thiosulphate and calcium disulphide or pentasulphide, depending on the proportions. This is the first reaction in making the official precipitated sulphur.

**278.**

If the lime water is added to the solution of lead subacetate the lead is partially precipitated as lead hydroxide, the amount increasing on standing. By adding the glycerin to the lead solution first the lime water causes no precipitation. The zinc oxide is insoluble and quickly settles to the bottom.

**279.**

There is some danger of causing an explosion in mixing these two chemicals. Even on mixing them in smaller amounts the chemical reaction is quite violent. There are white fumes given off and the mixture is turned brown. The odor of chlorine is soon lost. Chlorine oxidizes glycerin to oxalic and carbonic acids with intermediate products.

## 280.

On mixing these a heavy crystalline precipitate soon forms and it is difficult if not impossible to get an even dose. Potassium iodide combines with morphine sulphate. The physician should increase the amount of water and then increase the dose accordingly.

## 281.

Potassium permanganate oxidizes salicylic acid to formic acid and carbon dioxide and oxidizes the ferrous sulphate to ferric sulphate, while it is itself precipitated as manganese dioxide. There not being enough of acid to combine with all of the ferric iron, part of it is precipitated as a red-brown basic ferric salt, which with the black manganese dioxide makes a dark-brown mixture. When the solid matter settles there is left a violet-colored supernatant liquid. The violet color is due to the formation of ferric salicylate. There is not enough of permanganate to oxidize all of the salicylic acid or all of the ferrous sulphate.

## 282.

This gives a clear solution at first, but often on standing a heavy mass of crystals will form in a few hours. Sodium sulphite dissolves in about 2 parts of water but is nearly insoluble in alcohol. An excess of the salt is liable to be used as it is frequently effloresced. The alcohol in the spirit probably throws it out of solution and the ethyl nitrite may change it to the sulphate which is a little less soluble.

**283.**

Potassium permanganate oxidizes quinine sulphate to pyridin tricarboxylic acid, oxalic acid, and ammonia (M. & M., iv. 375). It also oxidizes the iron. When the permanganate and the iron are rubbed together a detonation takes place. The excipient should be one that will not reduce the permanganate, and it should also protect the other ingredients; a mixture of equal parts of paraffin, petrolatum, and kaolin is a good one, or resin cerate with althæa may be used.

**284.**

The strychnine will not dissolve in the glycerin or in the water. The consent of the prescriber to use strychnine sulphate or nitrate (the nitrate is the more common for hypodermic injection) should be obtained. In the absence of the prescriber the nitrate should be dispensed, notifying the prescriber of the change.

**285.**

If the menthol is dissolved in the spirit and then the water added the mixture becomes turbid, and on standing an oily liquid comes to the top, the menthol separating in that form instead of in crystals. This is probably not due to any effect of the ethyl nitrite or the acids usually present in the spirit, as a similar result is produced when alcohol is used in place of the spirit. The alcohol in the prescription clears it up but the solution turns red on account of the spirit of nitrous ether oxidizing resorcin.

**286.**

Sodium phosphate precipitates a solution of lithium bromide as lithium phosphate. There is more sodium phos-

phate than the water will dissolve. Heat should not be used to aid the solution, since on cooling large crystals will form. The phosphate should be powdered and the cold water allowed to dissolve what it will. Even then the part left undissolved may form a crystalline mass that can be gotten out of the bottle only by heating.

#### 287.

Podophyllin gives a black-brown color with the tincture of iron and nearly all is dissolved on warming. Quinine sulphate dissolves in this solution, and when the tincture of rhubarb is added the tannic acid in it precipitates the quinine, and with tincture of ferric chloride gives the black tannate of iron. The mixture is quite thick from the precipitated matter.

#### 288.

When camphor and carbolic acid are brought together a liquid results. In order to avoid making any more liquid than was necessary the corresponding amount of solid iodine was used in place of the tincture. The iodine dissolved readily in the phenol-camphor liquid and then the powdered lead acetate was added. Kaolin was tried as an absorbent excipient, but the amount required made the pills entirely too large. Starch was then used together with some glucose syrup, so as to form the easily decomposed iodide of starch. This made the pills very large and they were finally put into capsules.

#### 289.

The nitrohydrochloric acid oxidizes the hypophosphites to phosphates, but there is nothing in the appearance to indicate chemical reaction.

**290.**

Phenacetin is only sparingly soluble in water, but more soluble in alcohol, although there is not enough present in this prescription to dissolve it entirely, and what is dissolved is again thrown out of solution on adding the water. Heating the phenacetin with the tincture causes solution to take place, giving a dark-red color. On adding water the color is destroyed and the phenacetin is precipitated. The best way to fill this prescription is to powder the phenacetin, mix with a little acacia, and add the water and lastly the tincture of iron. Filled in this way the phenacetin is in a finer powder than when it is first dissolved in the tincture.

**291.**

The sodium salicylate and benzoate and the carbolic acid were dissolved in the lime water, making a nearly clear colorless solution, and then the tannic acid was added. A blue-white precipitate was formed, due to the reaction between the tannic acid and lime water. The precipitate afterwards slowly turned to a dirty-yellow color.

**292.**

This gave a clear solution at first but a turbidity was noticed within an hour and by the next morning the bottom of the bottle was covered with a white precipitate which responded to the tests for calomel. Mercuric chloride is slowly reduced to calomel by alcohol (M. & M., 1. 98). This does not explain the ready reduction that occurs, and the writer is inclined to think that the nitrous ether or acid has some effect, notwithstanding the fact that some writers say that nitrous acid does not reduce mercuric salts. (See P. & J., 4th ed., 203.)

## 293.

Iodoform dissolves rather slowly in ether and the solution begins to get brown red in a few minutes, deepening on standing. Iodine is liberated. Iodoform dissolves less readily in liquid petrolatum, but this solution slowly acquires a red color and liberates iodine.

## 294.

On adding olive oil to solution of lead subacetate a very thick liquid results, the subacetate making a good emulsion. The addition of phenol dissolved in glycerin causes no apparent change. If the glycerin solution of phenol is added to the solution of lead subacetate, white masses are formed and stick to the bottle. Adding the oil and shaking vigorously breaks up the masses somewhat but does not give as good a mixture as when filled by the first method.

## 295.

Adding the tincture to the syrup produces a gelatinous precipitate which dissolves on adding the acid. The precipitate is ferric hypophosphite which is decomposed by the phosphoric acid forming ferric phosphate which is soluble in excess of acid. If the prescriber had used hydrochloric acid instead of the phosphoric the precipitate would not have dissolved, the iron having a stronger affinity for the hypophosphorous acid than for hydrochloric but less than for the phosphoric.

**296.**

The quinine sulphate was dissolved in water with the aid of the acid and to this was added the alcoholic solution of the resorcin. A clear solution resulted but in a few minutes needle-shaped crystals began to form. By using quinine alkaloid instead of the sulphate the solution remains clear. The quinine sulphate seems to form a compound with resorcin, which is not very soluble in alcohol or water.

**297.**

By dissolving the morphine in a little water and adding it to the tincture of iron a blue solution is formed which quickly turns green. When the calcium hypophosphite, dissolved in the water and syrup, is added a white precipitate of ferric hypophosphite is thrown down. The color of the solution is nearly but not entirely destroyed. By adding the morphine dissolved in water to the mixture of other ingredients no coloration is produced, and this is the method that should be followed, as the morphine is not decomposed by the iron hypophosphite. The precipitate of ferric hypophosphite can be dissolved by adding some potassium citrate to the moist magma. A better method of filling is to use the tincture citrochloride of iron of the National Formulary instead of the official tincture of iron, the two tinctures having the same iron strength. By using it no precipitation takes place for several days at least.

**298.**

The doses of the first two ingredients are too large. The maximum dose of mercuric chloride is about  $\frac{1}{6}$  of a grain and of sodium arsenate about  $\frac{1}{9}$  of a grain. The prescription should not be dispensed without first consulting the prescriber. Should it be filled the potassium carbonate will react

with the strychnine, the mercury, and the iron salts, but the activity is not increased.

### 299.

The soap acts as an emulsifying and solidifying agent and the consistency of this mixture is about that of lard. Soap is nearly always alkaline and acts on the calomel, producing the black mercurous oxide. This explains why the mixture slowly turns dark.

### 300.

This prescription was filled by dissolving the quinine sulphate in a portion of the water with the aid of the acid; the potassium iodide dissolved in the balance of the water was added and lastly the sodium arsenate solution. The solution was clear and of a pale-yellow color. Within five minutes precipitation had commenced, and in less than fifteen minutes there was quite a heavy purple-red precipitate. Within a few hours a solid mass had formed which was of a purple-chocolate color. Sodium arsenate in the presence of an inorganic acid oxidizes potassium iodide, liberating iodine, and this precipitates the quinine. Using quinine bisulphate and leaving out the acid gives a solution that stands well.

### 301.

If the directions to use enough of the extract of glycyrrhiza to make a pill-mass be followed, the pills will be entirely too large. The best way is to melt one gram of beeswax, add the balsam and stir till the mixture is cool. Then use enough of powdered liquorice root to make the mass. Some would prefer to make twice the number of pills and double the dose.

### 302.

It is impossible for the dispenser to tell what the prescriber wanted. "Hyd." may stand for hydrochloric, hydro-

bromic, hydriodic, or hydrocyanic. From the directions to the patient to take after meals probably hydrochloric was what was intended, but it would be necessary to consult the physician.

### 303.

The difficulty is to get the arsenous acid into solution. Hynson (Bul. Pharm. xx. 301) suggests the use of the component parts of the tincture, which are alcohol and solution of ferric chloride. By dissolving the arsenous acid in the solution of iron and then adding the alcoholic solution of the bichloride and strychnine a clear solution is obtained. This is a principle that can be used to great advantage sometimes.

### 304.

On adding the zinc sulphate to the protargol solution a voluminous light brown precipitate forms and settles. The addition of about eighty minims of ammonia water clears it, and the morphine gives only a slight precipitate with it; on standing a dark green precipitate forms in a few hours and remains suspended. The prescription should be filled as written.

### 305.

In making ointments the medicinal ingredients must be in the form of a fine powder, soft solid, or solution. Iodine is powdered with difficulty. It might be dissolved in alcohol and this solution added to the lard. The U. S. Pharmacopœia directs that it be dissolved in an aqueous solution of potassium iodide, using one fourth as much potassium iodide as iodine and twice as much water as iodide. Lard will hold nearly 10 per cent. of its weight of water.

### 306.

This was filled by dissolving the quinine in a little water with the aid of the acid, adding the syrup, and lastly the potassium chlorate dissolved in the water. The solution was

clear and nearly colorless at first, but in a few minutes a red-brown precipitate began to form and increased until the mixture was quite thick. Sulphuric acid liberates chloric acid from the potassium chlorate, and this oxidizes the ferrous iodide, liberating iodine, which precipitates the quinine.

### 307.

Phenacetin requires 1400 parts of water or 6 parts of alcohol for solution. In filling this prescription the phenacetin can be dissolved in the tincture and spirit, but on adding the syrup and water nearly all of it will be thrown out of solution. A better mixture would be made by powdering the phenacetin with about two drams of acacia, then adding the syrup and part of the water, and lastly the tincture and spirit diluted with the balance of the water.

### 308.

An absorbent excipient is necessary in order to make a pill-mass. To use a powder like liquorice root or althæa would make the pills too large. Freshly calcined magnesia dampened with a little water is the best, as it is only necessary to use six or eight grains. The magnesia combines with the copaibic acid in the balsam to form a solid mass; a little water aids the reaction and it may be necessary to use the heat of a water-bath. The N. F. mass of copaiba can be used.

### 309.

This combination is an unusual one. The thiosulphate reduces calomel to metallic mercury, the mixture being darkened at once.

### 310.

Chloral hydrate rubbed with phenacetin gives a liquid, a sticky mass is also obtained when chloral hydrate is rubbed

with quinine sulphate. The phenacetin and quinine can be mixed and put into the capsules and then the chloral hydrate. Absorbent powder is hardly admissible, as each capsule contains fifteen grains of medicinal matter.

### 311.

The alcohol in the tincture is without any therapeutical value in this case, and only makes the pill-mass too soft. The alcohol should be evaporated before mixing with the other ingredients unless the extract of jalap has become dry and hard, in which case it can be used to soften the extract and then evaporated.

### 312.

The red color of Basham's mixture is changed by the citrated caffeine, giving a greenish yellow. The acetate and citrate of iron are both red but many of the double salts of iron are yellow to green and there may be a double salt here.

### 313.

When the acetanilide is added directly to the tincture of iron it makes a deep-red clear solution. On adding the water the acetanilide is precipitated and the color changed back to that of diluted tincture of iron. A better mixture can be made by powdering the acetanilide first, mixing with water and acacia or tragacanth, then adding the tincture of iron highly diluted with water. The tincture of iron, unless diluted with water, has a tendency to coagulate acacia. [See ACETANILIDUM, No. 2.]

### 314.

The hydrogen dioxide oxidizes the ferrous iron to a ferric salt and the glycerin to glyceric, oxalic, and tartaric acids, and in an acid solution reduces the bichromate to a green chromic salt. The hydrogen dioxide usually contains some mineral acid, which is left in to preserve it. In the presence

of free acid the bichromate oxidizes the ferrous sulphate and the glycerin. This prescription gives a heavy brown precipitate, probably of a basic ferric salt.

### 315.

So long as this mixture is kept from the light it does not change in color, but on exposure to direct sunlight for a few hours, or to diffused light for a longer period, it acquires a red color. This is due to the decomposition of iodoform, liberating iodine, and the iodine combines with and oxidizes the calomel, forming mercuric iodide.

### 316.

The trouble with this prescription is that the water breaks up the boroglycerin, liberating boric acid. Boric acid requires about 20 parts of water for solution, and there is not enough to dissolve it. By replacing one half of the water with glycerin no precipitation results.

### 317.

The salicylic acid is not soluble in the water and glycerin; it requires 308 parts of water for solution. If the acid is dissolved in the glycerin with the aid of heat and the tincture then added a clear solution results, but on adding the water a bulky crystalline precipitate comes down. A better method of filling is to rub the acid with the glycerin and water and then add the tincture. Free iodine reacts with salicylic acid, giving mono-, di-, and tri-iodobenzoic acids and tri-iodophenol (M. & M., III. 680). All of the iodine is not changed.

### 318.

The citrate of iron and quinine was dissolved in a part of the wine, making a clear acid solution. To this was added

the carbolic acid dissolved in the balance of the wine. A light-yellow sticky precipitate was formed. The composition of the precipitate was not determined, but on testing it quinine was proved to be present. Moreover, when iron citrate is used instead of the iron and quinine citrate no precipitation occurs. The precipitate is not dissolved by the further addition of the tincture, neither is precipitation prevented by adding a little dilute sulphuric acid. The tincture darkens the mixture a little and slightly increases the turbidity.

### 319.

Diuretin is sodium-theobromine salicylate and is readily soluble in water; acids decompose it. Theobromine differs from many alkaloids in that it does not readily combine with acids. In this prescription the diuretin was dissolved in the syrup, and then the spirit of nitrous ether added, and lastly the tincture of iron. When the iron is added a very deep violet color is produced, due to the formation of ferric salicylate, and on allowing the mixture to stand a few hours a white precipitate falls; the acids in the tincture and spirit liberate the theobromine and salicylic acid.

### 320.

Dissolving zinc sulphocarbolate in dilute solution of lead subacetate gives a white precipitate. A nearly clear solution can be obtained by dissolving the salt in an ounce of water, adding two drams of glycerin and then adding a mixture of the balance of the water and solution of lead subacetate corresponding with the amount of dilute solution which the prescription calls for.

### 321.

The pilocarpine differs from many alkaloids in that it is soluble in water. The hydrochloride is used much more fre-

quently than the free alkaloid. The terpin hydrate requires about 250 parts of water for solution; consequently only a small portion of it will be dissolved. A "Shake" label is necessary. A more elegant preparation would be made by emulsifying it.

### 322.

Menthol, chloroform, and liquid albolene make a clear mixture, but on shaking the mixture with the tincture it is made turbid and on standing separates into two layers. The upper one is nearly clear and colorless and the lower one is red and of small volume. Alcohol and the petrolatum oil do not remain mixed.

### 323.

An absorbent powder will be necessary to make a mass that can be put into capsules. When pyrocatechin is rubbed with acetanilide or phenacetin a liquid results. Acetanilide and phenacetin do not liquefy.

### 324.

This combination has perhaps caused more trouble than almost any other one prescription. The U. S. P. phosphate of iron may be a double compound of sodio-ferric citro-phosphate or it may be a mixture of ferric phosphate and sodium citrate. If it is the double compound (and there are reasons for thinking that it is) the phosphoric acid decomposes it, precipitating the phosphate of iron. If it is a mixture the explanation given is that the sodium citrate is readily soluble in water and an aqueous solution of it is a good solvent for the ferric phosphate. Now when phosphoric acid is added it is supposed that the sodium citrate is decomposed, forming sodium phosphate and citric acid; the ferric phosphate, being no longer soluble in this solution, is precipitated. This difficulty can be overcome by using strictly pure dilute

metaphosphoric acid (known also as glacial phosphoric acid) in place of the official orthophosphoric acid. A solution of metaphosphoric acid changes in time, forming some orthophosphoric acid, and if the meta-acid contain some of the ortho-variety a precipitation will occur. The dispenser must decide for himself as to the substitution proposed. There is sometimes, however, another difficulty present in this combination of ingredients. When quinine sulphate is present in a much larger proportion than two grains to the dram a precipitation of the quinine by the ortho- or the meta-acid takes place, and there seems to be no way to make a permanent solution. There is always some objection to dispensing a "Shake" mixture when it contains such an active agent as strychnine.

### 325.

In a neutral solution potassium iodide does not react with the tartrate of iron and potassium, but in the presence of the sulphuric acid the ferric salt oxidizes the iodide, liberating iodine. This iodine then combines with the quinine to form an insoluble compound. A "Shake well" label is necessary. If there were much more free iodine than would combine with the quinine the prescription should not be dispensed.

### 326.

The quinine sulphate was dissolved in the tincture of iron and a portion of the elixir added. The strychnine sulphate was dissolved in the balance of the elixir and added to the iron solution and the phosphoric acid added last. Adding the acid causes the formation of a nearly white precipitate which is phosphate of iron. If water is used in place of the elixir no precipitation results. The phosphate of iron is insoluble in water but soluble in acidulated water, and it is thrown out of solution by the alcohol in the elixir.

**327.**

This prescription was filled by rubbing the mercury with the iodine, then adding the glycerin, and lastly the tannic acid. Reaction takes place between the mercury and iodine, forming mercurous iodide and then mercuric iodide. Tannic acid reduces the iodine to hydriodic acid. Considerable red iodide of mercury is precipitated, although some is probably dissolved. This prescription is given in one of the standard works on therapeutics.

**328.**

The arsenite in alkaline solution reduces the iodine to an iodide while the arsenite becomes an arsenate. About one eighth of the iodine is reduced.

**329.**

This mixture if kept perfectly dry will not change in color, but pepsin is frequently hygroscopic and absorbs moisture in sufficient amount to enable a reaction to take place between the calomel and sodium bromide, causing the powder to turn black. Sodium bromide in the presence of moisture breaks up calomel, forming a mercuric compound and metallic mercury, the latter giving the dark color. Theoretically one half of the calomel goes to form mercuric chloride, and if this is really so there would be about one fourth of a grain of mercuric chloride to the dose which would be dangerous.

**330.**

Sodium bicarbonate is used in making the solution of saccharin, and while this solution makes a clear one with the strychnine at first yet on standing over night the strychnine is precipitated. There is not enough of alcohol in the saccharin solution to prevent it. The strychnine frequently adheres to the sides of the bottle, but may be loose, and in that case an overdose is liable to be taken.

**331.**

The glycerite of boroglycerin which is called for can be mixed with the vaselin, but it separates on standing. Using lanolin in place of vaselin no separation occurs.

**332.**

The organic matter in the infusion changes the iodine so that it no longer gives a test with starch. The benefit derived from the iodine is questionable.

**333.**

The glycerin was added to the tincture of myrrh, then the solution of potassium chlorate in small amounts with continued shaking, and the tincture of iron last. Tincture of iron gives a dark green-brown color with tincture of myrrh. Water precipitates the resinous matter from the tincture of myrrh, and it forms in masses that cannot be evenly suspended. It seems to make but little difference whether the alcoholic mixture is added to the aqueous or the aqueous to the alcoholic. By using honey instead of glycerin the resin is separated but does not form masses, consequently it can be evenly distributed through the liquid.

**334.**

The fluidextracts and elixir are sufficiently acid so that chemical reaction takes place between the potassium nitrite and the organic matter. Considerable effervescence ensues and continues for some time. Oxides of nitrogen are given off. A slight precipitate forms on standing. Probably much of the physiological activity of the mixture is destroyed by the chemical reaction.

**335.**

A mixture of these ingredients quite quickly separates into two layers, the lower one being about one fourth the

total volume. There is not sufficient alcohol to dissolve the other liquids. There is no effervescence at first, but if the bottle is tightly corked it may be burst by the gas which is slowly evolved. The liquid becomes red brown on standing.

**336.**

A clear solution was obtained which had at first a dark violet color. The color soon changed to brown, and in a few hours a dark-brown precipitate began to form. The amount of precipitate continued to increase for some time. It was filtered out, thoroughly washed with water, and heated with water acidulated with hydrochloric acid; part went into solution and part remained undissolved. The filtrate showed the presence of iron. The part left undissolved is probably some oxidation product of carbolic acid, produced by the chlorine liberated by the acid in the tincture acting on the potassium chlorate.

**337.**

The color of this mixture is brown at first, due to the free iodine. The iodine soon combines with the free oleic acid, forming addition products which are nearly colorless.

**338.**

There is a sufficient amount of water to dissolve the potassium salts and the solution remains clear for a time after the spirit is added. It is not long, however, before crystals begin to separate. The alcohol in the spirit throws the potassium chlorate out of solution.

**339.**

When the two prescriptions are mixed in the proportions as directed the result is almost a mass. Reaction takes place between silver nitrate and potassium iodide, forming the insoluble silver iodide. It is customary to filter all preparations

intended to be dropped into the eyes, but in this case the prescriber wanted the solid matter left in. The solution marked No. 1, containing silver nitrate, began to darken within an hour, due to the reduction of silver. This reduction continued for some time. Solution No. 2 turned yellow in a few days.

### 340.

Most of the medicinal matter will be thrown out of solution. The possible reactions are as follows: Tannin gives the insoluble compounds of mercuric tannate, morphine tannate, and lead tannate; mercuric chloride gives lead chloride; morphine sulphate with solution of lead subacetate gives an insoluble double compound and also lead sulphate. Glycerin will keep the precipitates suspended.

### 341.

Filled as directed this prescription gives a nearly colorless mixture which does not give a test for free iodine. On standing two layers are formed, the upper being about one third of the volume of the lower. The upper layer consists chiefly of turpentine, while the lower consists of the alcohol containing some oil of turpentine and an iodide of mercury. Leaving out either the turpentine or mercuric chloride, the iodine is not all reduced. If the mercuric chloride is left out the lower layer is smaller in volume and is nearly colorless, while the upper one is chiefly alcohol containing free iodine. The turpentine is the principal factor in reducing the iodine. The mercuric chloride perhaps acts as a carrier or acts by breaking up the compound which iodine forms with the oil, thereby allowing the oil to combine with more iodine.

### 342.

On inquiry it was found that this prescription was for a horse. It makes a turbid, deep red mixture, the red color being due to the action of spirit of nitrous ether on aloin.

**343.**

Although a clear solution is produced at first, within a few minutes a crystalline precipitate begins to form. Piperazine is quite strongly alkaline and causes a precipitation of the strychnine. As written this should be considered a dangerous combination. The difficulty can be remedied by neutralizing the piperazine solution with dilute sulphuric acid.

**344.**

Camphor and menthol dissolve in liquid alboline, which is a purified liquid petrolatum; cocaine hydrochloride does not dissolve. The free alkaloid cocaine should be used as it dissolves.

**345.**

A mixture of these ingredients makes a clear colorless solution at first. Antipyrine destroys the fluorescence of quinine sulphate. A white amorphous precipitate forms in a day or two and increases in amount for some time. If the prescription is filled, using distilled water instead of cinnamon water, no precipitation results. The trouble seems to be due to antipyrine, sulphuric acid, and cinnamon water, since a mixture of any two or three ingredients of the prescription other than the combination mentioned does not precipitate.

**346.**

Trional and salol produce a soft mass when rubbed together, and a drying powder is necessary.

**347.**

This prescription was filled by mixing the first four ingredients and putting into capsules and then dropping in the tincture. The next day the box in which the capsules were dispensed was brought back, the capsules had been dissolved. Sodium bromide attracts moisture from the atmosphere. Antipyrine with caffeine citrate makes a mixture that forms a sticky mass on standing a few hours. A mixture of all the ingredients makes a damp powder at first, but in a few hours it becomes almost liquid. A large amount of drying powder is necessary.

**348.**

The bottle containing this mixture should not be stoppered tightly or it may be burst. Infusion of digitalis is acid in reaction and slowly liberates carbon dioxide gas from ammonium carbonate.

**349.**

There is a sufficient amount of alcohol and water to prevent the gold salt from precipitating strychnine. However, the gold is reduced in a few hours, largely by the alcohol but partly by the syrup. The gold as precipitated has a purplish color by transmitted light but yellow or brown by reflected light.

**350.**

The potassium acetate was dissolved in water and the spirit added. Effervescence ensued and continued for a few minutes, but ceased after several shakings. Alcohol effervesces a little when mixed with water, but not nearly as much as the above mixture did. Onewriter (Scoville, 301) says that nitrous acid converts acetates into carbon monoxide and other gases. This explanation is not satisfactory since about

as much effervescence results when spirit of nitrous ether is added to a strong solution of Rochelle salt, sodium chloride, or potassium nitrate. It has been suggested that the potassium acetate or other salt throws the ethyl nitrite out of solution in the mixture of alcohol and water and that the volatilization of the ethyl nitrite is the cause of the effervescence. There is much less effervescence when the solutions have been well chilled before mixing.

A TABLE SHOWING THE EFFECT OF RUBBING TOGETHER EQUAL WEIGHTS OF TWO SOLIDS.

[illegible]

**L** = Soft mass or liquid.

M = Stiff mass which dries.

P = Dry powder.

P' = Slightly damp powder, quickly drying.

P2 = Said to liquify, but the writer obtained a dry powder.

## TABLE OF SOLUBILITIES.

If the compounds are official the solubilities are those given by the Pharmacopœia, usually at 25° C. In other cases the solubility is generally at ordinary temperature.

	Water.	Alcohol.	Ether.	Chloro- form.	Glycerin.
Theobromine . . . . .	sp. s.	sp. s.	sol.		
Thiocol . . . . .	sol.	sp. s.	ins.		
Thioform . . . . .	ins.	ins.	ins.	.....	sol.
Thiol . . . . .	sol.	sol.	sp. s.	.....	sol.
Thymoform . . . . .	ins.	sol.	sol.	sol.	ins.
Thymol . . . . .	1100	1	1	1	
Iodide . . . . .	ins.	sp. s.	v. s.	v. s.	ins.
Tolyantipyrine . . . . .	10	sol.	ins.		
Trional . . . . .	320	v. s.	v. s.		
Triphenin . . . . .	2000	sol.	sol.		
Tumenol . . . . .	ins.	sol.	sol.		
Uranium Nitrate . . . . .	sol.	sol.	sol.		
Urea . . . . .	1	5	ins.	ins.	
Urethane . . . . .	v. s.	0.6	1	1.3	3
Urotropine . . . . .	1.5	10	228		
Salicylate . . . . .	sol.	sol.			
Vanillin . . . . .	100	v. s.	v. s.	v. s.	v. s.
Veratrine, U. S. P. . . . .	1750	2.2	3	1	
Veronal . . . . .	145	sol.	v. s.	sol.	
Xeroform . . . . .	ins.	ins.			
Zinc Acetate . . . . .	2.5	36			
Bromide . . . . .	v. s.	v. s.	sol.		
Carbonate . . . . .	ins.	ins.	ins.		
Chloride . . . . .	0.4	v. s.	sol.	.....	2
Cyanide . . . . .	ins.	ins.			
Iodide . . . . .	v. s.	v. s.	.....	.....	2.5
Lactate . . . . .	58	ins.			
Nitrate . . . . .	v. s.	sol.			
Oxide . . . . .	ins.	ins.			
Phenolsulphonate . . . . .	1.7	1.7			
Phosphide . . . . .	ins.	sol.			
Salicylate . . . . .	20	v. s.	v. s.		
Sulphate . . . . .	0.53	ins.	.....		3
Stearate . . . . .	ins.	ins.	ins.		
Sulphocarbonate . . . . .	1.7	1.7			
Tannate . . . . .	ins.	ins.			
Valerate . . . . .	50	35	sp. s.		

## TABLE OF PRICES.

AVERAGE OF PRICES CHARGED IN THE VARIOUS SECTIONS OF THE UNITED STATES FOR PRESCRIPTIONS NOT REQUIRING EXTRAORDINARY SKILL OR CALLING FOR ANY VERY EXPENSIVE INGREDIENT.

LIQUIDS.		POWDERS, CAPSULES, OR PILLS.	
1 ounce,	\$0.20-0.25	1 to 4,	\$0.15-0.25
2    "	0.30-0.35	5 to 6,	0.25-0.30
3    "	0.35-0.40	8,	0.30-0.35
4    "	0.40-0.50	10,	0.35-0.40
6    "	0.60-0.65	12,	0.40
8    "	0.75	24,	0.50-0.75
OINTMENTS.		SUPPOSITORIES.	
$\frac{1}{2}$ ounce,	\$0.25	$\frac{1}{2}$ dozen,	\$0.40-0.50
1    "	\$0.30-0.35	1    "	0.75-1.00
2    "	0.40-0.50		

## INDEX TO INCOMPATIBILITIES.

pyrophosphoric .....	24	chloride .....	40

Ammonium iodide .....	40	Bromoform .....	54
salts .....	40	Bromine .....	54
valerate .....	40	Butyl chloral hydrate .....	55
Amyl nitrite .....	41		
Amylum .....	41	Cacao butter .....	97
Antimony and potassium tartrate ..	41	Cadmium salts .....	55
sulphide .....	42	Caffeine .....	55
Antipyrine .....	42	Calcium betanaphthol sulphonate ..	51
dimethylamido .....	106	hypophosphite .....	56
Apomorphine hydrochloride .....	44	phosphate .....	56
Aqua .....	45	salts .....	56
Aqua ammoniæ .....	45	Calomel .....	80
chlori .....	89	Calx .....	56
hydrogenii dioxidi .....	46	chlorata .....	56
Aquæ .....	46	sulphurata .....	57
Argenti nitras .....	47	Cambogia .....	57
oxidum .....	48	Camphor .....	57
Argonin .....	49	monobromated .....	58
Aristochin .....	49	Cannabis indica .....	58
Aristol .....	115	Cantharidin .....	58
Arsenic iodide .....	49	Carbo .....	58
pentoxide .....	50	Carbonates .....	59
trioxide .....	50	Catechu .....	60
Arsenates .....	50	Cerium oxalate .....	60
Arsenites .....	50	Charcoal .....	58
Asaprol .....	51	Chloral alcoholate .....	61
Aspirin .....	51	hydrate .....	60
Atropine .....	52	Chloralamid .....	60
Auri et sodii chloridum .....	52	Chlorates .....	61
		Chloretone .....	62
Balsam of copaiba .....	65	Chlorides .....	16
Barium salts .....	53	Chlorine .....	62
Benzaldehyde .....	95	Chloroform .....	62
Benzoates .....	7	Chromates .....	63
Betanaphthol .....	53	Chrysarobin .....	64
salicylate .....	53	Cinchona .....	64
Betol .....	53	Citrates .....	10
Bicarbonates .....	59	Citrophen .....	64
Bismuth and ammonium citrate .....	53	Cocaine .....	64
oxidogallate .....	34	Codeine .....	64
subgallate .....	53	Colchicine .....	65
subnitrate .....	53	Collodion .....	65
subsalicylate .....	54	Colloidal mercury .....	83
Borates .....	8	Coniine .....	65
Bromal hydrate .....	54	Copaiba .....	65
Bromides .....	15	Copper sulphate .....	66

Corrosive sublimate . . . . .	77	Glucosides . . . . .	74
Creosotal . . . . .	66	Glycerin . . . . .	74
Creosote . . . . .	66	Glyceritum boroglycerini . . . . .	75
carbonate . . . . .	66	Glycerinophosphates . . . . .	74
Cresol . . . . .	66	Glyceryl trinitrate . . . . .	76
Cupri sulphas . . . . .	66	Glycyrrhizin, ammoniated . . . . .	76
Cyanides . . . . .	17	Gold and sodium chloride . . . . .	52
Decoctions . . . . .	67, 85	Guaiac resin . . . . .	76
Dermatol . . . . .	53	Guaiacol . . . . .	76
Digitalis . . . . .	67	carbonate . . . . .	76
Diuretin . . . . .	67	Helmitol . . . . .	77
Duotal . . . . .	76	Heroine hydrochloride . . . . .	77
Elaterin . . . . .	68	Hexamethylenamine . . . . .	77
Emulsions . . . . .	68	Holocaine hydrochloride . . . . .	77
Ergot . . . . .	68	Homatropine . . . . .	77
Erythrol tetranitrate . . . . .	68	Honey . . . . .	92
Ether . . . . .	33	Hydrargyri chloridum corrosivum . . . . .	77
acetic . . . . .	33	chloridum mite . . . . .	80
Ethyl bromide . . . . .	33	cyanidum . . . . .	82
carbamate . . . . .	33	iodidum flavum . . . . .	82
iodide . . . . .	33	iodidum rubrum . . . . .	82
Ethylene bichloride . . . . .	33	oxidum flavum . . . . .	83
Eucaïne . . . . .	68	subsulphas flavus . . . . .	83
Eucalyptol . . . . .	68	Hydrargyrum ammoniatum . . . . .	83
Eugenol . . . . .	96	colloidale . . . . .	83
Euphorin . . . . .	68	Hydrates, fixed alkali . . . . .	90
Europhen . . . . .	68	Hydrate, volatile alkali . . . . .	45
Exalgine . . . . .	69	Hydrogen dioxide . . . . .	46
Ferric salts . . . . .	70	Hydroquinone . . . . .	84
Ferri phosphas solubilis . . . . .	69	Hyoscyamine . . . . .	84
pyrophosphas solubilis . . . . .	69	Hyoscyamus . . . . .	84
Ferripyrin . . . . .	69	Hypochlorites . . . . .	56
Ferrous salts . . . . .	72	Hypophosphites . . . . .	18
Ferrum . . . . .	73	Hyposulphites . . . . .	112
Fluidextracts . . . . .	74	Hyrgol . . . . .	83
Formaldehyde . . . . .	89	Ichthyol . . . . .	84
Formalin . . . . .	89	Infusions . . . . .	85
Fowler's solution . . . . .	90	Iodates . . . . .	85
Gallates . . . . .	11	Iodides . . . . .	13
Gambir (see Catechu).		Iodine . . . . .	86
Gamboge . . . . .	57	Iodoform . . . . .	85
Gelatin . . . . .	74	Iodol . . . . .	86
Glonoin . . . . .	76	Iodophenacetin . . . . .	86
		Iodophenin . . . . .	86

Iron (metallic) .....	73	Methylthioninæ hydrochlor. ....	93
